On the decomposition of Global Conformal Invariants II

Spyros Alexakis
February 2, 2008

Abstract

This paper is a continuation of [2], where we complete our partial proof of the Deser-Schwimmer conjecture on the structure of “global conformal invariants”. Our theorem deals with such invariants $P(g^n)$ that locally depend only on the curvature tensor $R_{ijkl}$ (without covariant derivatives).

In [2] we developed a powerful tool, the “super divergence formula” which applies to any Riemannian operator that always integrates to zero on compact manifolds. In particular, it applies to the operator $I_{g^n}(\phi)$ that measures the “non-conformally invariant part” of $P(g^n)$. This paper resolves the problem of using this information we have obtained on the structure of $I_{g^n}(\phi)$ to understand the structure of $P(g^n)$.

1 Introduction

We briefly recall the open problem that this paper and [2] address and the theorem that we will be completing here. Our objects of study are scalar Riemannian invariants $P(g^n)$ of a Riemannian manifold $(M^n, g^n)$. These are polynomials in the components of the tensors $R_{ijkl}, \ldots, \nabla^m R_{ijkl}, \ldots$ and $g^{ij}$ (or, even more generally, in the variables $\hat{g}^{t_1 \ldots t_k} \cdot g_{t_1 \ldots t_k}, \text{det}(g)^{-1}$), that are independent of the coordinate system in which they are expressed, and also have a weight $W$, meaning that under a re-scaling $g^n \rightarrow t^2 g^n$ they transform by $P(t^2 g^n) = t^W P(g^n)$, $t \in \mathbb{R}_+$. It is a classical result that such invariants are linear combinations

$$P(g^n) = \sum_{l \in L} a_l C^l(g^n)$$

of complete contractions in the form:

$$\text{contr}(\nabla^{m_1}_{r_1 \ldots r_{m_1}} R_{ijkl} \otimes \cdots \otimes \nabla^{m_s}_{t_1 \ldots t_{m_s}} R^{i'j'k'l'})$$

each with weight $W$. We fix an even dimension $n$ once and for all, and we restrict attention to local scalar invariants of weight $-n$. Due to the transformation of the volume form $dV_{e^{2\phi(x)}} g^n = e^{n \phi(x)} dV_{g^n}$ under general conformal re-scalings $\hat{g}^n \rightarrow e^{2\phi(x)} g^n$, it follows that if $P(g^n)$ has weight $-n$ then the quantity $\int_{M^n} P(g^n) dV_{g^n}$ is scale-invariant for any compact orientable Riemannian $(M^n, g^n)$. 
The problem we are addressing is to find all Riemannian scalar invariants of weight \(-n\) for which the integral \(\int_{M^n} P(g^n) dV_{g^n}\) is invariant under conformal re-scalings \(\hat{g}^n = e^{2\phi(x)} g^n\) for any compact manifold \((M^n, g^n)\) and any \(\phi \in C^\infty(M^n)\). In other words, we are assuming that for any \((M^n, g^n)\) and \(\phi \in C^\infty(M^n)\) we must have:

\[
\int_{M^n} P(g^n) dV_{g^n} = \int_{M^n} P(\hat{g}^n) dV_{\hat{g}^n} \quad (3)
\]

Deser and Schwimmer, two physicists, conjectured the following in [10]:

**Conjecture 1 (Deser-Schwimmer)** Suppose we have a Riemannian scalar \(S(g^n)\) of weight \(-n\) for some even \(n\). Suppose that for any compact manifold \((M^n, g^n)\) the quantity

\[
\int_{M^n} S(g^n) dV_{g^n} \quad (4)
\]

is invariant under any conformal change of metric \(\hat{g}^n(x) = e^{2\phi(x)} g^n(x)\). Then \(P(g^n)\) must be a linear combination of three "obvious candidates", namely:

\[
S(g^n) = W(g^n) + \text{div}_i T_i(g^n) + c \cdot \text{Pfaff}(R_{ijkl}) \quad (5)
\]

1. \(W(g^n)\) is a scalar conformal invariant of weight \(-n\), i.e., it satisfies \(W(\hat{g}^n) = e^{-n\phi(x)} W(g^n)\) for every \(\phi \in C^\infty(M^n)\) and every \(x \in M^n\).

2. \(T_i(g^n)\) is a Riemannian vector field of weight \(-n + 1\). (Since for any compact \(M^n\) we have \(\int_{M^n} \text{div}_i T_i(g^n) dV_{g^n} = 0\).)

3. \(\text{Pfaff}(R_{ijkl})\) stands for the Pfaffian of the curvature \(R_{ijkl}\). (Since for any compact Riemannian \((M^n, g^n)\) \(\int_{M^n} \text{Pfaff}(R_{ijkl}) dV_{g^n} = \frac{2^\frac{n}{2} \pi^{\frac{n}{2}} (\frac{n}{2} - 1)!}{2^{n-1} (n-1)!} \chi(M^n)\).)

In this paper we complete our partial confirmation of this conjecture. We restrict our attention to Riemannian scalars \(P(g^n)\) that are linear combinations

\[
\Sigma_{l \in L} a_l C^l(g^n) \quad (6)
\]

of complete contractions of weight \(-n\), each \(C^l(g^n)\) in the form:

\[
\text{contr}(R_{i_1 j_1 k_1 l_1} \otimes \cdots \otimes R_{i_r j_r k_r l_r}) \quad (7)
\]

(since we are not allowing derivatives on the factors \(R_{ijkl}\), the weight restriction forces each complete contraction to have \(\frac{n}{2}\) factors). The main theorem that we show in [2] and in the present paper is:

**Theorem 1** Let us suppose that \(P(g^n)\) is in the form \((6)\), where each \(C^l(g^n)\) is in the form \((7)\), with \(r = \frac{n}{2}\) factors. We also assume that \((3)\) holds for any Riemannian \((M^n, g^n)\) and \(\phi \in C^\infty(M^n)\).
Then, there exists a scalar conformal invariant \( W(g^n) \) of weight \(-n\) that locally depends only on the Weyl tensor, and also a constant \( c \) so that:

\[
S(g^n) = W(g^n) + c \cdot \text{Pfaff}(R_{ijkl})
\]

where \( \text{Pfaff}(R_{ijkl}) \) stands for the Pfaffian of the curvature \( R_{ijkl} \).

We will recall two related results that were proven by entirely different methods. In \cite{17} Gilkey considered the problem of finding all scalar invariants \( P(g^n) \) of weight \(-n\) for which \( \int_{M^n} P(g^n) dV_{g^n} \) is constant for a given compact orientable \( M^n \) and any Riemannian metric \( g^n \) over \( M^n \). He then showed that:

**Theorem 2 (Gilkey)** Under the above assumptions, we have that \( P(g^n) \) can be written as:

\[
P(g^n) = \text{div}_i T_i(g^n) + c \cdot \text{Pfaff}(R_{ijkl})
\]

where \( T_i(g^n) \) is an intrinsic vector field of weight \(-n+1\) and \( \text{Pfaff}(R_{ijkl}) \) stands for the Pfaffian of the curvature tensor.

(see also \cite{24} for an earlier form of this result). Extending the methods in \cite{17}, Branson, Gilkey and Pohjanpelto showed in \cite{5} that:

**Theorem 3 (Branson-Gilkey-Pohjanpelto)** Consider any local Riemannian invariant \( P(g^n) \) of weight \(-n\), with the property that for any manifold \( M^n \) and any locally conformally flat metric \( h^n \), \( \int_{M^n} P(h^n) dV_{h^n} \) is invariant under conformal re-scalings \( \hat{h}^n = e^{2\phi(x)} h^n \) of the metric \( h^n \). It then follows that in the locally conformally flat metric \( h^n \) (for which the Weyl tensor vanishes), we can write out:

\[
P(h^n) = \text{div}_i T_i(h^n) + c \cdot \text{Pfaff}(R_{ijkl})
\]

where \( T_i(h^n) \) is a vector field of weight \(-n+1\) and \( \text{Pfaff}(R_{ijkl}) \) stands for the Pfaffian of the curvature tensor.

We have explained in \cite{2} how resolving the whole of the Deser-Schwimmer conjecture would have implications regarding the structure of the so-called \( Q \)-curvature, and also for the study of conformally compact Einstein manifolds, in particular regarding the notions of the re-normalized volume and the conformal anomaly, see also \cite{11, 12, 18, 21, 20, 23}. Here, we briefly recall the definition of \( Q \)-curvature.

\( Q \)-curvature is a Riemannian scalar invariant \( Q^n(g^n) \) constructed by Branson for each even dimension \( n \) (see \cite{4}). In dimension 2 it is just the scalar curvature \( (Q^2(g^2) = R) \) and in dimension 4 (where it has been extensively studied), it is in the form:

\[
Q^4(g^4) = \frac{1}{12} \left( -\Delta R + \frac{1}{4} R^2 - |E|^2 \right)
\]

where \( R \) is the scalar curvature and \( E \) is the traceless Ricci tensor.
In dimension \( n \), \( Q^n(g^n) \) has weight \(-n\). Its two main properties are that
\[
\int_{M^n} Q^n(g^n) dV_{g^n}
\]
is invariant under conformal changes of \( g^n \) and that under the re-scaling \( g^n \to e^{2\phi(x)} g^n \), \( Q^n(g^n) \) enjoys the transformation law:
\[
Q^n(e^{2\phi(x)} g^n)(x) = e^{-n\phi(x)}[Q^n(g^n) + P_n^\phi(\phi)](x)
\]
where \( P_n^\phi(\phi) \) is a conformally co-variant differential operator, originally constructed in [19]. Conformal co-variance means that its symbol has a nice transformation law under the conformal re-scaling \( \hat{g}^n = e^{2\phi(x)} g^n \), namely for every \( g^n, \phi, \psi \in C^\infty(M^n) \):
\[
P_{e^{2\psi(x)} g^n}^\phi(\phi) = e^{-n\psi(x)} P_{g^n}^\phi(\phi)
\]
The above transformation law has played an important role in the analysis surrounding \( Q \)-curvature (see [7], [6] for example). Moreover, the particular form of \( Q^4(g^4) \) and its relation to the Chern-Gauss-Bonnet integrand has proven to be a valuable tool in geometric and topological applications of \( Q \)-curvature in dimension 4, see [8], [25]. Therefore, understanding of the structure of \( Q \)-curvature in high dimensions would raise the question whether the powerful techniques employed in the study of \( Q \)-curvature in dimension 4 can be extended to higher dimensions.

2 Formulas and an outline of the proof.

Throughout this paper we will be employing all the notational and terminological conventions from [2]. We will also be heavily using Theorem 2 in that paper and its two corollaries regarding identities that hold “formally” or “by substitution”, see also [3], [13], [26].

We recall that \( P(g^n) \) satisfies [3]. In [2] we defined an operator \( I_{g^n}(\phi) \) as:
\[
I_{g^n}(\phi) = e^{n\phi(x)} P(e^{2\phi(x)} g^n) - P(g^n)
\]
which has weight \(-n\) and the fundamental property that:
\[
\int_{M^n} I_{g^n}(\phi) dV_{g^n} = 0
\]
for every compact Riemannian \((M^n, g^n)\).

As our tool for this paper will be the super divergence formula for \( I_{g^n}(\phi) \), it is necessary to write out \( P(g^n) \) in such a way so that we can “recover” the non-conformally invariant part of \( P(g^n) \) from the expression of \( I_{g^n}(\phi) \). As an illustration of the difficulty that we are forced to address, we suppose that we write out \( P(g^n) \) as a linear combination of contractions in the form [7]. But then, given the transformation law for the curvature tensor, it is not obvious
how to reconstruct $P(g^n)$ if we are given $I_g^n(\phi)$.

In order to overcome this difficulty, we recall the Schouten tensor as a trace-adjustment of Ricci curvature:

$$P_{\alpha\beta} = \frac{1}{n-2} \left[ Ric_{\alpha\beta} - \frac{R}{2(n-1)} g^n_{\alpha\beta} \right]$$  \hspace{1cm} (16)

Where $Ric_{\alpha\beta}$ stands for Ricci curvature and $R$ stands for scalar curvature.

We then have the well-known decomposition of the curvature tensor:

$$R_{ijkl} = W_{ijkl} + \left[ P_{jk} g^n_{il} + P_{il} g^n_{jk} - P_{jl} g^n_{ik} - P_{ik} g^n_{jl} \right]$$  \hspace{1cm} (17)

The Weyl tensor is trace-free and conformally invariant, i.e., for $\hat{g}^n = e^{2\phi} g^n$:

$$W_{ijkl}^{\hat{g}^n} = e^{2\phi(x)} W_{ijkl}^g$$  \hspace{1cm} (18)

While the Schouten tensor has the following transformation law:

$$P_{\hat{\alpha}\hat{\beta}}^{\hat{g}^n} = P_{\alpha\beta}^g - \phi_{\alpha\beta} + \phi_{\alpha} \phi_{\beta} - \frac{1}{2} \phi^k \phi_k g^n_{\alpha\beta}$$  \hspace{1cm} (19)

In view of our assumption for Theorem 1 and equation (17), we may now write $P(g^n)$ in the form:

$$P(g^n) = \sum_{l \in L} a_l C^l(g^n)$$  \hspace{1cm} (20)

where each complete contraction $C^l(g^n)$ is in the form:

$$\text{contr}(W_{i_1 j_1 k_1 l_1} \otimes \cdots \otimes W_{A_1 A_2 A_3 A_4} \otimes P_{a_1 b_1} \otimes \cdots \otimes P_{a_B b_B})$$  \hspace{1cm} (21)

Because of the weight restriction, we see that $A + B = \frac{n}{2}$.

Let us break up the index set $L$ into subsets $L^{\mu,\nu}$ as follows: $l \in L^{\mu,\nu}$ if and only if $C^l(g^n)$ is in the above form and $A = \mu, B = \nu$.

We then notice that the linear combination:

$$P^1(g^n) = \sum_{l \in L^{\mu,\nu}} a_l C^l(g^n)$$

is a scalar conformal invariant of weight $-n$. Hence, in view of the claim of our Theorem 1, we may subtract it off, and we are left with considering the case where $P(g^n)$ is a linear combination:

$$P(g^n) = \sum_{l \in L} a_l C^l(g^n)$$

where each complete contraction $C^l(g^n)$ is in the form (21) with $B \geq 1$.

We then have the main theorem of this paper:
**Theorem 4** Suppose we are given a $P(g^n)$ which is a linear combination of complete contractions of weight $-n$, each in the form (21) with $B \geq 1$ and $P(g^n)$ satisfies (3). Suppose we know the coefficient of the complete contraction $(P_n^a)^{\frac{B}{2}}$ in $P(g^n)$.

Then there can be at most one linear combination $P(g^n)$ of complete contractions in the form (21) with $B \geq 1$ for which the condition (3) holds.

If we can show the above, our Theorem 1 will follow. In order to see this, observe that for each even dimension $n$, we have that Pfaff $(R_{ijkl})$ cannot be a linear combination of complete contractions depending only on the Weyl curvature: If for some $n$ that were the case, we would have that for the $n$-sphere $S^n$ with the standard locally conformally flat metric $\int_{S^n} \text{Pfaff}(R_{ijkl})dV_{g^n} = 0$, which is absurd by the Chern-Gauss-Bonnet Theorem.

Thus, if we write out Pfaff $(R_{ijkl})$ as a linear combination of complete contractions in the form (21) and define $\text{Pfaff}(R_{ijkl})$ to stand for the sublinear combination of the complete contractions in Pfaff $(R_{ijkl})$ with $A = 0$, $B = \frac{n}{2}$, so that (3) holds.

This implies our main theorem. □

We will prove Theorem 4 by the following two Lemmas:

**Lemma 1** Given the coefficient of the complete contraction $(P_n^a)^{\frac{B}{2}}$, there can be at most one sublinear combination of complete contractions $C_i(g^n)$ of the form (21) in $P(g^n)$ with $A = 0$, $B = \frac{n}{2}$ so that (3) holds.

**Lemma 2** Given an integer $1 \leq A_1 \leq \frac{n}{2} - 1$, and given the sublinear combination of the complete contractions $C_i(g^n)$ in $P(g^n)$ with $A < A_1$, then there can be at most one sublinear combination of complete contractions $C_i(g^n)$ of the form (21) in $P(g^n)$ with $A = A_1$ so that (3) holds.

It is clear that if we can prove the above two Lemmas, then by induction Theorem 4 will follow. In the rest of the paper we give the proof of these Lemmas.

Our main tool in the proof will be the super divergence formula and the shadow divergence formula used on the operator $I(g^n)(\phi)$.

A disclaimer on our use of these formulas is in order. We will no longer be needing the polarized form $I^{Z}_g(\psi_1, \ldots, \psi_Z)$ of $I^{Z}_g(\phi)$. We will be referring to the super divergence formula of $I^{Z}_g(\phi)$, and we will mean the formula that arises from $\text{supdiv}[I^{Z}_g(\psi_1, \ldots, \psi_Z)]$ by setting $\psi_1 = \cdots = \psi_Z = \phi$ and dividing by $Z!$. The same will apply when we refer to the shadow divergence formula of $I^{Z}_g(\phi)$. 

6
We must also recall a few more simple facts from [2]. We recall that $I^m_{\phi} (\phi)$ is taken to be a linear combination of complete contractions in the form:

$$\text{contr}(\nabla_{r_1} \cdots \nabla_{r_m} R_{ijkl} \otimes \cdots \otimes \nabla_{t_1} \cdots \nabla_{t_m} R_{ijkl} \otimes \nabla_{a_1} \phi \otimes \cdots \otimes \nabla_{b_1} \phi)$$

(23)

We also recall that in the context of the iterative integrations by parts, the $\xi$-contractions that we generically encounter are in the form:

$$\text{contr}(\nabla_{r_1} \cdots \nabla_{r_m} R_{i_1j_1k_1l_1} \otimes \cdots \otimes \nabla_{t_1} \cdots \nabla_{t_m} R_{i_1j_1k_1l_1} \otimes \nabla_{a_1} \phi \otimes \cdots \otimes \nabla_{b_1} \phi)$$

(24)

where the factors $\nabla^m R_{ijkl}$ are allowed to have internal contractions among the indices $i, j, k, l$.

Upon occasion, we will be writing those complete contractions as linear combinations of complete contractions in the forms:

$$\text{contr}(\nabla_{r_1} \cdots \nabla_{r_m} R_{i_1j_1k_1l_1} \otimes \cdots \otimes \nabla_{t_1} \cdots \nabla_{t_m} R_{i_1j_1k_1l_1} \otimes \nabla_{a_1} \phi \otimes \cdots \otimes \nabla_{b_1} \phi)$$

(25)

$$\text{contr}(\nabla_{r_1} \cdots \nabla_{r_m} R_{i_1j_1k_1l_1} \otimes \cdots \otimes \nabla_{t_1} \cdots \nabla_{t_m} R_{i_1j_1k_1l_1} \otimes \nabla_{a_1} \phi \otimes \cdots \otimes \nabla_{b_1} \phi)$$

(26)

One immediately sees that we can write each complete contraction in the form (24) or (25) as a linear combination of contractions in the forms (24) or (25) by repeated use of the identity:

$$[\nabla_i \nabla_j - \nabla_j \nabla_i] X_k = R_{ijkl} X^l$$

(27)

We must also recall the transformation law of the curvature tensor, along with that of the Levi-Civita connection, under conformal re-scalings $\hat{g}^a = e^{2\phi(x)} g^a$:

$$R^a_{ijkl} = e^{2\phi(x)} [R^a_{ijkl} + \phi_{ik} g_{jl} - \phi_{jk} g_{il} - \phi_{ij} g_{lk} + \phi_{ik} g_{jl} - \phi_{jk} g_{il} - \phi_{il} g_{kj} - |\nabla \phi|^2 g_{ik}]$$

(28)

$$\nabla_k^a \eta_l = \nabla_k^a \eta_l - \phi_l \eta_k + \phi^a \eta_k g^a_{kl}$$

(29)

Next, we will prove certain Lemmas that will be useful throughout this paper.
2.1 Useful Lemmas.

Our first Lemma is the following:

**Lemma 3** Suppose we are given a collection of complete contractions $C^k_{g^n}(\phi)$, $k \in K$ of weight $-n$ and in the form (25) or a collection of complete contractions $C^k_{g^n}(\phi, \tilde{\xi})$, $k \in K$, each in the form (26). Suppose that the identities, respectively:

$$\sum_{k \in K} a_k C^k_{g^n}(\phi) = 0 \quad (30)$$

$$\sum_{k \in K} a_k C^k_{g^n}(\phi, \tilde{\xi}) = 0 \quad (31)$$

hold for every Riemannian manifold $(M^n, g^n)$ at any point $x_0$ and for any function $\phi$ defined around $x_0$, and in the second case for any vector $\tilde{\xi} \in \mathbb{R}^n$. We define subsets $K^{(r_1,\ldots,r_Z)}$ of the index set $K$ as follows: $k \in K^{(r_1,\ldots,r_Z)}$ if and only if $C^k_{g^n}(\phi)$, which is in the form (25), satisfies $\nu_1 = r_1, \ldots, \nu_Z = r_Z$, where the values $\nu_1, \ldots, \nu_Z$ are taken in decreasing rearrangement.

Then, for any subset $K^{(r_1,\ldots,r_Z)} \subset K$, we will have, respectively:

$$\sum_{k \in K^{(r_1,\ldots,r_Z)}} a_k C^k_{g^n}(\phi) = 0 \quad (32)$$

$$\sum_{k \in K^{(r_1,\ldots,r_Z)}} a_k C^k_{g^n}(\phi, \tilde{\xi}) = 0 \quad (33)$$

for any Riemannian manifold $(M^n, g^n)$ at any point $x_0$ and for any function $\phi$ defined around $x_0$, and in the second case for any vector $\tilde{\xi} \in \mathbb{R}^n$.

**Proof:** We only have to observe that the relations (30) and (31) hold formally, where we regard the tensors $\nabla_{\nu_1,\ldots,\nu_{r_v}} \phi$ as symmetric $p$-tensors $\Omega_{\nu_1,\ldots,\nu_{r_v}}$. On the other hand, the values $\nu_1, \ldots, \nu_Z$ remain invariant under the permutation relations of Definitions 7 and 8 in [2]. Hence, we have our Lemma. □

Our second Lemma will be the following:

**Lemma 4** Let us suppose we are given complete contractions $C^k_{g^n}(\phi)$ in the form (25), and that the identity:

$$\sum_{k \in K} a_k C^k_{g^n}(\phi)(x_0) = 0$$

holds on any Riemannian manifold $(M^n, g^n)$ and for any function $\phi$ around $x_0$. Let us suppose that the minimum length among the complete contractions $\{C^k_{g^n}(\phi)\}_{k \in K}$ is $L$. Then let us define the subset $K^\sharp \subset K$ as follows: $k \in K^\sharp$ if and only if $C^k_{g^n}(\phi)$ which is in the form (26), has length $L$ and also has no internal contractions. We then have that:

$$\sum_{k \in K^\sharp} a_k C^k_{g^n}(\phi) = 0 \quad (34)$$

modulo complete contractions of length $\geq L + 1$. 
Proof: Let us begin by defining the set $K_1 \subset K$ as follows: $k \in K_1$ if and only if $C^k_{g^n}(\phi)$ has length $L$. Obviously, $K^k \subset K_1$.

Now, we want to apply Theorem 2 in [2]. For each complete contraction $C^k_{g^n}(\phi), k \in K_1$, we consider its linearization $\text{lin}C^k(R, \phi)$. Then, by the Lemma hypothesis and Theorem 2 in [2], we have that the equation:

$$
\sum_{k \in K} a_k \text{lin}C^k(R, \phi) + \sum_{k \in K_1 \setminus K} a_k \text{lin}C^k(R, \phi) = 0 \quad (35)
$$

will hold formally. But then notice the following: For any linearized complete contraction $\text{lin}C^k(R, \phi)$, the number of internal contractions remains unaltered under any of the linearized permutation identities. Hence, (35) implies that:

$$
\sum_{k \in K^k} a_k \text{lin}C^k(R, \phi) = 0
$$

formally. But then, as in the proof of the corollaries of Theorem 2 in [2], we have that:

$$
\sum_{k \in K^k} a_k C^k_{g^n}(\phi) = 0 \quad \text{modulo complete contractions of length } \geq L + 1. \quad \square
$$

3 The easier step: Proof of Lemma\[1\]

Consider any complete contraction $C^l(g^n)$ in the form (21) with $A = 0$. Let us denote by $R[C^l(g^n)]$ the number of factors $P^a_{ab}$ in $C^l(g^n)$. Also, let $L^0, L^\lambda, \lambda$ stand for the subset of $L$ which is defined as follows: $l \in L^0, L^\lambda, \lambda$ if and only if $l \in [0, L^\lambda]$ and $R[C^l(g^n)] = \lambda$.

We will show Lemma\[1\] by an inductive statement. We assume that for some $T \geq 0$, we have determined the sublinear combinations $\sum_{l \in L^0, L^\lambda, \lambda} a_l C^l(g^n)$, for each $\lambda \geq T + 1$. We will then show that we can determine the sublinear combination $\sum_{l \in L^0, L^\lambda, \lambda} a_l C^l(g^n)$. If we can prove this inductive step, then it is obvious that our Lemma will follow.

In order to prove the above, we consider $I_{g^n}(\phi)$. For any $C^l(g^n)$ with $l \in L^0, L^\lambda$, we define $C_{g^n}(\phi)$ to be the complete contraction which is obtained from $C^l(g^n)$ by substituting each factor $P_{ab}$ by $-\nabla_{ab}^2\phi$.

By virtue of (19) and the definition of $I_{g^n}(\phi)$ we have that:

$$
I_{g^n}(\phi) = \sum_{l \in L^0, L^\lambda, \lambda} a_l C_{g^n}(\phi)
$$

modulo complete contractions of length $\geq \frac{3}{2} + 1$. In particular, each $C^l(g^n)$ with $l \in L^A, A \geq 1$ will not contribute to the above.

So the problem is reduced to determining the sublinear combination $\sum_{l \in L^0, L^\lambda, \lambda} a_l C_{g^n}(\phi)$ of complete contractions $C_{g^n}(\phi)$ with $T$ factors $\Delta\phi$.
the sublinear combination $\sum_{r=0}^{n-1} \Sigma_{i \in L} \frac{1}{2} \tau a_i C_{g^n}^r (\phi)$ of complete contractions $C_{g^n}^r (\phi)$ with more than $T$ factors $\Delta \phi$.

We will use the formula $\text{supdiv} [I_{g^n}^T (\phi)]$. Let us make a definition:

Consider any complete contraction $C_{g^n}^l (\phi)$, $l \in L^0, T$. It will be in the form:

$$\text{contr} (\nabla_{a_{1b_1}}^2 \phi \otimes \cdots \otimes \nabla_{a_{2b_2}}^2 \phi \otimes \Delta \phi \otimes \cdots \otimes \Delta \phi)$$

where none of the factors $\nabla_{a_{ib_i}}^2 \phi$ is in the form $\Delta \phi$.

We consider the complete contraction $C_{g^n}^{l,D} (\phi)$:

$$\text{contr} (\nabla^{i_1 \cdots i_T} [\nabla_{a_{1b_1}}^2 \phi \otimes \cdots \otimes \nabla_{a_{2b_2}}^2 \phi] \otimes \nabla_{i_1} \phi \otimes \cdots \otimes \nabla_{i_T} \phi)$$

We write out $C_{g^n}^{l,D} (\phi)$ as a linear combination $\Sigma_{r \in R} a_r C_{g^n}^r (\phi)$, where each $C_{g^n}^r (\phi)$ is in the form:

$$\text{contr} (\nabla_{r_1 \cdots r_m}^2 \phi \otimes \cdots \otimes \nabla_{r_{m+1} \cdots r_{m+n}}^2 \phi \otimes \nabla_{i_1} \phi \otimes \cdots \otimes \nabla_{i_T} \phi)$$

where each $m_i \geq 2$ and each index $i_s$ contracts against an index in a factor $\nabla^{m_s} \phi$. For each such complete contraction $C_{g^n}^r (\phi)$, we define $SC_{g^n}^r (\phi)$ to be:

$$\text{contr} (S \nabla_{r_1 \cdots r_m}^2 \phi \otimes \cdots \otimes S \nabla_{r_{m+1} \cdots r_{m+n}}^2 \phi \otimes \nabla_{i_1} \phi \otimes \cdots \otimes \nabla_{i_T} \phi)$$

(36)

Observe that, modulo complete contractions of length $\geq \frac{n}{2} + 1$, $C_{g^n}^l (\phi) = SC_{g^n}^r (\phi)$.

For any $l \in L^0, T$, we write out $Tail[C_{g^n}^l (\phi)]$ as a linear combination of complete contractions in the form $2^{2m}$. We have that:

$$Tail[C_{g^n}^l (\phi)] = \Sigma_{r \in R} a_r SC_{g^n}^r (\phi) + \Sigma_{j \in J} a_j C_{g^n}^j (\phi)$$

(37)

modulo complete contractions of length $\geq \frac{n}{2} + 1$. Each complete contraction $C_{g^n}^l (\phi)$ has length $\frac{n}{2}$ and less than $T$ factors $\nabla \phi$.

Now, for any complete contraction $C_{g^n}^l (\phi)$, $l \in L^0, T$, we have that:

$$Tail[C_{g^n}^l (\phi)] = \Sigma_{a \in V} a_C C_{g^n}^a (\phi)$$

where each complete contraction $C_{g^n}^r (\phi)$ has either length $\geq \frac{n}{2} + 1$ or has length $\frac{n}{2}$ but less than $T$ factors $\nabla \phi$. This follows from formula $2^{2m}$.

The super divergence formula can be expressed as:

$$\Sigma_{\lambda=0}^{T-1} \Sigma_{\ell \in L} \frac{1}{2} \tau a_{\ell} Tail[C_{g^n}^l (\phi)] + \Sigma_{\ell \in L} \frac{1}{2} \tau a_{\ell} Tail[C_{g^n}^l (\phi)] +$$

$$\Sigma_{\lambda=T+1}^{\frac{n}{2}-1} \Sigma_{\ell \in L} \frac{1}{2} \tau a_{\ell} Tail[C_{g^n}^l (\phi)] = 0$$

(38)
modulo complete contractions of length $\geq \frac{n-1}{2} + 1$.

We consider, in (38), the sublinear combination $supdiv[I_g^n]|_{\nabla \phi = T}$ of complete contractions of length $\frac{n}{2}$ with $T$ factors $\nabla \phi$. From Lemma 8 we have that

$$supdiv[I_g^n]|_{\nabla \phi = T} = 0 \quad (39)$$

Furthermore, in view of formula (38) and our observations above, we have the following: Let $\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]|_{\nabla \phi = T}$ denote the sublinear combination in $\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]$ of complete contractions with $T$ factors $\nabla \phi$, then:

$$sdI_{\nabla \phi = T} = \Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]|_{\nabla \phi = T} + \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l [\Sigma_{r \in R} a_r SC_{g^n}^r(\phi)] = 0 \quad (40)$$

Now, by our inductive hypothesis, we are assuming that we know the sublinear combination $\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l C_{g^n}^l(\phi)$. Hence, we deduce that we can determine the sublinear combination $\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]$. Therefore, we can also determine the sublinear combination $\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]|_{\nabla \phi = T}$, and using (40), we determine the sublinear combination $\Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l [\Sigma_{r \in R} a_r SC_{g^n}^r(\phi)]$.

A notational convention: When we write $(\nabla)^a$ we will mean that we are taking one covariant derivative $\nabla_a$ and then raising the index $a$. (This is to distinguish from $\nabla^a$ which stands for a iterated covariant derivatives). We will now give the following values to factors of the complete contractions in (40): To each factor $\nabla_x \phi$ we give the value of $-P_{ab}(x_0)$. Also, to each expression of the from $\nabla_{r_1 \ldots r_p} \phi(\nabla)^{r_1} \phi \ldots (\nabla)^{r_p} \phi$ (where $\{c, d\} = \{r_1, \ldots, r_p\} \setminus \{r_1, \ldots, r_{p-2}\}$) we give the value $-P_{cd} \cdot (P_a^n)^{p-2}$. For that assignment $A$ of values, we have that:

$$(n - T)^T \cdot \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l C_{g^n}^l + A(\Sigma_{\lambda=T+1}^{-1} \Sigma_{l \in L^0} \frac{\partial}{\partial a_l} a_l Tail[C_{g^n}^l(\phi)]|_{\nabla \phi = T} = 0$$

This concludes the proof of Lemma 8. \(\square\)

4 The harder step: Proof of Lemma 2

We want to determine the coefficients of the various complete contractions $C_{g^n}^l$, indexed in $L^{A_1, 2 A_1}$.

We consider $I_{g^n}^{2 A_1}(\phi)$. For any $C_{g^n}^l$, $l \in L^{A_1, 2 A_1}$, we define $C_{g^n}^l(\phi)$ to be the complete contraction which is obtained from $C_{g^n}^l$ by substituting each factor $P_{ab}$ by $-\nabla_{ab} \phi$. We then have that:
modulo complete contractions of length $\geq \frac{n}{2} + 1$. The complete contractions $C_{g^n}^l(\phi)$ are in the form (25) and they arise from the sublinear combination $\sum_{k=\frac{n}{2}+1}^{\infty} \sum_{l \in L} \phi_k a_l C^l(g^n)$. Hence, we have that the sublinear combination $\sum_{a \in U} a_n C_{g^n}^n(\phi)$ is known.

The complete contractions $C_{g^n}^l(\phi)$ are in the form:

$$\text{contr}(W_{i_1,j_1,k_1,l_1} \otimes \cdots \otimes W_{i_N,j_N,k_N,l_N} \otimes \nabla_{a_1 b_1} \phi \otimes \cdots \otimes \nabla_{a_N b_N} \phi)$$

(41)

While we write the complete contractions $C_{g^n}^l(\phi)$ in the form:

$$\text{contr}(R_{i_1,j_1,k_1,l_1} \otimes \cdots \otimes R_{i_N,j_N,k_N,l_N} \otimes \nabla_{a_1 b_1} \phi \otimes \cdots \otimes \nabla_{a_N b_N} \phi)$$

(42)

(for this equation, the factors $R_{ijkl}$, $\nabla_{ab} \phi$ are allowed to have internal contractions).

Now, we write $\sum_{l \in L \setminus A_1} \nabla_{a \cdot} a_l C^l(g^n)(\phi)$ as a linear combination:

$$\sum_{l \in L \setminus A_1} \nabla_{a \cdot} a_l C^l(g^n)(\phi) = \sum_{a \in U} a_u C_{g^n}^u(\phi)$$

(43)

where each $C_{g^n}^u(\phi)$ is in the form:

$$\text{contr}(R_{ijkl} \otimes \cdots \otimes R_{i'j'k'l'} \otimes \text{Ric}_{kl} \otimes \cdots \otimes \text{Ric}_{k'l'} \otimes R \otimes \cdots \otimes R \otimes \nabla_{a_{\beta}} \phi \otimes \cdots \otimes \nabla_{a_{\beta}} \phi \otimes \Delta \phi \otimes \cdots \otimes \Delta \phi)$$

(44)

When we employ the above notation we will imply that each of the factors $R_{ijkl}$, $\text{Ric}_{ab}$ and $\nabla_{ab} \phi$ does not have any of the indices $i, j, k, l$ or $a, b$ or $\alpha, \beta$ contracting between themselves. Let $Z$ stand for the number of factors $R_{ijkl}$, $X$ for the number of factors $\text{Ric}_{ab}$, $C$ for the number of factors $R$, $\Gamma$ for the number of factors $\nabla_{\alpha \beta} \phi$ and $\Delta$ for the number of factors $\Delta \phi$. We have that $Z + X + C = A_1$ and $\Gamma + \Delta = \frac{n}{2} - A_1$.

We denote the corresponding index set in $U$ by $U^{Z,X,C,\Gamma,\Delta}$. We then claim the following:

**Lemma 5** Under the assumptions of Lemma 4 we claim that we can determine all the sublinear combinations $\sum_{u \in U^{Z,X,C,\Gamma,\Delta}} a_u C_{g^n}^u(\phi)$ above.

Before we prove this Lemma, let us explain how we can deduce our desired Lemma 4 from Lemma 5.

If we can determine all the sublinear combinations $\sum_{u \in U^{Z,X,C,\Gamma,\Delta}} a_u C_{g^n}^u(\phi)$, we then have determined the whole linear combination $\sum_{u \in U} a_u C_{g^n}^u(\phi)$, and hence by 18 we will have determined the linear combination $\sum_{l \in L \setminus A_1} \nabla_{a \cdot} a_l C^l(g^n)(\phi)$.

But then, setting $\nabla_{a b} \phi(x_0) = -P_{ab}(x_0)$, we determine $\sum_{l \in L \setminus A_1} \nabla_{a \cdot} a_l C^l(g^n)$, and hence we will have shown our Lemma.
4.1 The long induction: The Proof of Lemma

We will determine the various sublinear combinations by an induction.

We initially determine the sublinear combination \( \sum_{u \in U^{0.1,A_1-1.1}} \mathcal{V}^n - A_1 - 1 a_u C^n_u (\phi) \).

By definition, we see that the sublinear combination in question will be of the form \((\text{const}) \cdot C^n_u (\phi)\), where \(C^n_u (\phi)\) is the complete contraction:

\[
\text{const} (R^{A_1 - 1} \otimes \text{Ric}^{ab} \otimes \nabla^2_{ab} \phi \otimes (\Delta \phi) \mathcal{V}^{A_1 - 1})
\]

(Thus determining \( \sum_{u \in U^{0.1,A_1-1.1}} \mathcal{V}^n - A_1 - 1 a_u C^n_u (\phi) \) amounts to determining \((\text{const})\)).

Then, we will determine the sublinear combination \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \).

We observe that this sublinear combination will be in the form:

\[
(\text{const})' \cdot \text{const} (R^{A_1} \otimes (\Delta \phi) \mathcal{V}^{A_1})
\]

(Thus again, we only have to determine \((\text{const})'\)).

Finally, having determined the two sublinear combinations above, we will prove the following inductive statement: Let us suppose that for some number \(\Delta_1 + 1\), we have determined all the sublinear combinations \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \) with \(\Delta \geq \Delta_1 + 1\). Moreover, we assume that for some number \(C_1 + 1\), we have determined all the sublinear combinations \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \) with \(C \geq C_1 + 1\). Finally, we suppose that for some number \(X_1 + 1\), we have determined all the sublinear combinations \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \) with \(X \geq X_1 + 1\). We then claim that we can determine the sublinear combination \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \). If we can show the above then by induction we will have proven our Lemma.

Before proceeding with the proof, we make note of how the Weyl tensor can be decomposed:

\[
W_{ijkl} = R_{ijkl} + \frac{1}{n-2} [\text{Ric}_{ik} g^n_{jl} + \text{Ric}_{jl} g^n_{ik} - \text{Ric}_{il} g^n_{jk} - \text{Ric}_{jk} g^n_{il}]
\]

\[
- \frac{R}{(n-1)(n-2)} g^n_{ik} g^n_{jl} + \frac{R}{(n-1)(n-2)} g^n_{il} g^n_{jk}
\]

\((47)\)

**Determining the sublinear combination \( \sum_{u \in U^{0.0,A_1-1.0}} \mathcal{V}^n - A_1 a_u C^n_u (\phi) \):**

We consider \(I^{\mathcal{V} - A_1 + 1}_g (\phi)\). We focus on the sublinear combinations of complete contractions of length \(\frac{n}{2} - 1\) or \(\frac{n}{2} + 1\) in \(I^{\mathcal{V} - A_1 + 1}_g (\phi)\), which we respectively denote by \(I^{\mathcal{V} - A_1 + 1}_g (\phi)\) and \(I^{\mathcal{V} - A_1 + 1}_g (\phi)\). Using the transformation law \((49)\) and the conformal invariance of the Weyl tensor, we deduce that the sublinear combination \(I^{\mathcal{V} - A_1 + 1}_g (\phi)\) arises from the sublinear combination \(\sum_{B=0}^{A_1 - 1} \sum_{L \in B} \mathcal{V} - A_1 a_L C^n_L (g^n) \) in \(P(g^n)\). Therefore by our inductive hypothesis, we have that the sublinear
contraction \( I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \lvert_{Z + 1} \) in \( I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \) is known.

Now, we also claim that the sublinear combination \( I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \lvert_{Z + 1} \) in \( I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \) can be written as:

\[
I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \lvert_{Z + 1} = \Sigma_{k \in K} a_k C_{g^n}^k(\phi) + \Sigma_{u \in U_1} a_u C_{g^n}^u(\phi) \tag{48}
\]

where \( \Sigma_{k \in K} a_k C_{g^n}^k(\phi) \) arises from \( \Sigma_{B = 0}^{A_1 - 1} \Sigma_{l \in L}^{\frac{n}{2} - B} a_l C^l(g^n) \) in \( P(g^n) \) and \( \Sigma_{u \in U_1} a_u C_{g^n}^u(\phi) \) arises from the sublinear combination \( \Sigma_{l \in L, A_1 - 1} \phi \) in \( P(g^n) \). This means that the contractions \( C^l(g^n), l \in L, B \leq A_1 + 1 \) will not contribute to \( I_{g^n}^{\frac{n}{2} - A_1 + 1}(\phi) \lvert_{Z + 1} \). This follows by virtue of [19]. Hence, we may assume that the sublinear combination \( \Sigma_{k \in K} a_k C_{g^n}^k(\phi) \) is known.

Now, we initially have that the complete contractions \( C_{g^n}^u(\phi) \) on the right hand side of the above are in the form:

\[
contr(W_{i_1 j_1 k_1 l_1} \cdots W_{i_A j_A k_A l_A} \nabla^2_{a_1 b_1} \phi \cdots \nabla^2_{a_{A_1 - 1} b_{A_1 - 1} a_{A_1 - 1} b_{A_1 - 1} - A - 1} \phi \otimes \nabla_x \phi \otimes \nabla_d \phi) \tag{49}
\]

Then, we decompose the Weyl tensor as in (17) and we write the linear combination on the right hand side of the above as a linear combination of complete contractions in the form:

\[
contr(R_{i_1 j_1 k_1 l_1} \cdots R_{i_A j_A k_A l_A} \nabla^2_{a_1 b_1} \phi \cdots \nabla^2_{a_{A_1 - 1} b_{A_1 - 1} a_{A_1 - 1} b_{A_1 - 1} - A - 1} \phi \otimes \nabla_x \phi \otimes \nabla_d \phi \otimes (\Delta \phi)^r) \tag{50}
\]

where we are making the notational convention that no two indices in any factor \( R_{ijkl}, \nabla \phi \) are contracting between themselves. We write:

\[
\Sigma_{u \in U_1} a_u C_{g^n}^u(\phi) = \Sigma_{u \in U_2} a_u C_{g^n}^u(\phi)
\]

where each \( C_{g^n}^u(\phi) \), \( u \in U_2 \) is in the form [50]. We replace the expression \( \Sigma_{u \in U_2} a_u C_{g^n}^u(\phi) \) for \( \Sigma_{u \in U_1} a_u C_{g^n}^u(\phi) \) in [18]. Moreover, we assume that each \( C_{g^n}^u(\phi) \) in [18] is in the form [50].

Now, we focus on the sublinear combination in \( \Sigma_{u \in U_2} a_u C_{g^n}^u(\phi) \) that consists of complete contractions in the form [50] with \( Z = 0 \) factors \( R_{ijkl} \), \( Y = 1 \) factor \( Ric_{\phi} \), \( C = A_1 - 1 \) factors \( R \), \( \Gamma = 0 \) factors \( \nabla^2 \phi \), \( \Delta = \frac{n}{2} - A_1 - 1 \) factors \( \Delta \phi \).

We also assume that the two factors \( \nabla \phi \) contract against the two indices of the one factor \( Ric_{\phi} \). Therefore, we have that the sublinear combination in question is of the form \((const)_{\phi} \cdot C_{g^n}^u(\phi)\), where \( C_{g^n}^u(\phi) \) is in the form:

\[
contr(R^{A_1 - 1} \otimes Ric^{ij} \otimes \nabla_i \phi \otimes \nabla_j \phi \otimes (\Delta \phi)^r) \tag{51}
\]

We now make two claims:
Lemma 6 We have that the sublinear combination \( (\text{const}) \cdot C_{g^n}^l (\phi) \) in \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) arises from the sublinear combination \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) in \( I_{g^n}^{\frac{n}{2} - A_1} (\phi) \) by replacing the factor \( \nabla_i^2 \phi \) by an expression \( -\nabla_i \phi \nabla_j \phi \).

Our second claim is that the sublinear combination \( (\text{const}) \cdot C_{g^n}^l (\phi) \) can be determined from the known sublinear combinations in \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) using the shadow divergence formula for \( I_{g^n}^{\frac{n}{2} - A_1 + 1} (\phi) \).

We observe that if we can show the above Lemma, we will then have determined the sublinear combination \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) in \( I_{g^n}^{\frac{n}{2} - A_1} (\phi) \), and hence proven the first base case of our induction.

Proof of Lemma 6 We begin with the first part. Initially, let us focus on the sublinear combination \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) in \( I_{g^n}^{\frac{n}{2} - A_1} (\phi) \) and understand in detail how it arises. For each \( l \in L^{A_1 + 1} \frac{n}{2} - A_1 \), we consider the complete contraction \( C_{g^n}^l (\phi) \) defined above, which will be in the form \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \). We then decompose the factors \( W_{ijkl} \) as in \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \).

Now, for each factor \( W_{ijkl} \), we have the option of replacing it by one of the 7 expressions on the right hand side of \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \). Therefore, we can write \( C_{g^n}^l (\phi) \) as a sum of \( 7^{A_1} \) complete contractions in the form \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \)

\[
C_{g^n}^l (\phi) = \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi)
\] (52)

Each of the \( 7^{A_1} \) different summands corresponds to a different sequence of substitutions of the \( A_1 \) factors \( W_{ijkl} \) as explained above. We then group up the complete contractions \( C_{g^n}^u (\phi) \) on the right hand side of the above that are of the form \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \), and we denote that sublinear combination in \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) by \( F[C_{g^n}^l (\phi)] \). Hence, using this notation we have that:

\[
\Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) = \Sigma_{l \in L^{A_1 + 1}} F[C_{g^n}^l (\phi)]
\]

Now, we consider the complete contractions in \( \text{Image}_{\phi}^{\frac{n}{2} - A_1 + 1} C^l (g^n) \), for each \( l \in L^{A_1 + 1} \frac{n}{2} - A_1 \). We are only interested in the sublinear combination

\[
\text{Image}_{\phi}^{\frac{n}{2} - A_1 + 1} C^l (g^n) + 1
\]

of complete contractions of length \( \frac{n}{2} + 1 \). It follows that this sublinear combination arises by replacing the \( \frac{n}{2} - A_1 - 1 \) factors \( P_{ab} \) by the expression \( -\nabla_{ab} \phi \) on the right hand side of \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \) and also by replacing one factor \( P_{ab} \) by a quadratic expression on the right hand side of \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \).

Now, we further denote by \( \text{Image}_{\phi}^{\frac{n}{2} - A_1 + 1} C^l (g^n) \) the sublinear combination in \( \text{Image}_{\phi}^{\frac{n}{2} - A_1 + 1} C^l (g^n) \) that arises when we replace the \( \frac{n}{2} - A_1 - 1 \) factors \( P_{ab} \) by \( -\nabla_{ab} \phi \) and one factor \( P_{ab} \) by the expression \( g_{ab} \phi \phi \). We trivially observe that if we write out \( \text{Image}_{\phi}^{\frac{n}{2} - A_1 + 1} C^l (g^n) \) as a linear combination of complete contractions in the form \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \), none will be in the form \( \Sigma_{u \in U^l} a_u C_{g^n}^u (\phi) \).
Hence, we may restrict our attention to the sublinear combination
\( \text{Image}^g\bar{\phi}^{-A_1+1} - [C^l(g^n)] \) in \( \text{Image}^g\bar{\phi}^{-A_1+1} - [C^l(g^n)] \) that arises when we replace \( \bar{\phi}^{-A_1+1} \) factors \( P_{ab} \) by \( -\nabla^2_{ab} \phi \) and one factor \( P_{ab} \) by \( \nabla_a \phi \nabla_b \phi \). Hence, comparing \( \text{Image}^g\bar{\phi}^{-A_1} \{ \Sigma_{\ell \in L^A_1} \bar{\phi}^{-A_1} a_1 C^l(g^n) \} \) and \( \text{Image}^g\bar{\phi}^{-A_1+1} \{ \Sigma_{\ell \in L^A_1} \bar{\phi}^{-A_1} a_1 C^l(g^n) \} \), we see that \( \text{Image}^g\bar{\phi}^{-A_1+1} \{ \Sigma_{\ell \in L^A_1} \bar{\phi}^{-A_1} a_1 C^l(g^n) \} \) arises from \( \text{Image}^g\bar{\phi}^{-A_1} \{ \Sigma_{\ell \in L^A_1} \bar{\phi}^{-A_1} a_1 C^l(g^n) \} \) by picking out one factor \( \nabla^2_{ab} \phi \) from each complete contraction in the form [41] in \( \text{Image}^g\bar{\phi}^{-A_1} \{ \Sigma_{\ell \in L^A_1} \bar{\phi}^{-A_1} a_1 C^l(g^n) \} \) (this factor may now also be of the form \( \Delta \phi \) and replacing it by an expression \( -\nabla_a \phi \nabla_b \phi \). In that case, if we repeat the decomposition of the factors \( W_{ijkl} \) to the complete contractions in \( \text{Image}^g\bar{\phi}^{-A_1+1} - [C^l(g^n)] \), we obtain the first claim of our Lemma.

Now, for the second part of our Lemma, we first of all denote \( (\text{const})C^n_g(\phi) \) by \( \Sigma_{u \in U^2} a_u C^n_g(\phi) \). We then want to apply the shadow divergence formula to \( I_{g^n}^{-A_1+1} \) (\( \phi \)) and determine the sublinear combination \( \Sigma_{u \in U^2} a_u C^n_g(\phi) \). We will focus on the sublinear combination of \( \bar{\xi} \)-contractions in \( \text{Shad}[I_{g^n}^{-A_1+1}] \) that are in the form:

\[
\text{contr}((|\xi|^2)^{-A_1-1} \otimes S \nabla_{r_1}^{-A_1} \bar{\xi} \nabla_{r_1}^{-A_1+1} \otimes \nabla^{r_1} \phi \otimes \cdots \otimes \nabla^{r_{A_1+1}}) \phi \] (53)

If we denote the sublinear combination of those \( \bar{\xi} \)-contractions in \( \text{Shad}[I_{g^n}^{-A_1+1}] \) by \( \text{Shad}_+[I_{g^n}^{-A_1+1}] \), we claim that:

\[
\text{Shad}_+[I_{g^n}^{-A_1+1} \phi] = 0 \] (54)

This is straightforward because the shadow divergence formula holds formally. Now, for each \( k \in K \) (see [18]) we denote by \( Tail^\text{Shad}_+[C^n_g(\phi)] \) the sublinear combination in each \( Tail^\text{Shad}_+[C^n_g(\phi)] \) that consists of \( \xi \)-contractions in the form [51]. Analogously, for each \( u \in U_2 \), we denote by \( Tail^\text{Shad}_+[C^n_g(\phi)] \) the sublinear combination in each \( Tail^\text{Shad}_+[C^n_g(\phi)] \) that consists of \( \xi \)-contractions in the form [51]. Now, we observe that the \( \xi \)-length of the \( \bar{\xi} \)-contraction in [51] is \( \frac{1}{2} + 1 \). Hence, in view of the Lemma on acceptable descendants in [2] and also [18], [51], we deduce that:

\[
\text{Shad}_+[I_{g^n}^{-A_1+1}(\phi)] \frac{1}{2} = Tail^\text{Shad}_+[\Sigma_{k \in K} d_k C^n_g(\phi)] + Tail^\text{Shad}_+[\Sigma_{u \in U^2} a_u C^n_g(\phi)] = 0
\] (55)

Therefore, if we could show that for each \( u \in U_2 \setminus U_1^* \), we have that:

\[
\text{Shad}_+[C^n_g(\phi)] = 0
\] (56)

we could then use equation [51] to determine the sublinear combination

\[
\Sigma_{u \in U^2} a_u Tail^\text{Shad}_+[C^n_g(\phi)].
\]
Let us observe how it would then be straightforward to determine $\Sigma_{u \in U^2} a_u C_g^u(\phi)$.

We claim that for $u \in U^2$, $Tail^{Shad}[C_g^u(\phi)] = (-1)^{\frac{n}{2} - A_1} C_g^u(\phi, \xi)$. To see this, we note that $Tail^{Shad}[C_g^u(\phi)]$ arises in the following way: Let us denote by $C_g^u(\psi, \xi)$ the descendant of $C_g^u(\phi)$ that arises by replacing the $A_1 - 1$ factors $R$ by $|\xi|^2$, the $\frac{n}{2} - A_1 - 1$ factors $\Delta \phi$ by $\nabla_i \phi \xi_i$ and the factor $Ric_{ij}$ by $-\nabla_i \xi_j$ (all in $N$-cancelled notation). Recall from [2] that $O^{Shad}[C_g^u(\phi, \xi)]$ stands for the sublinear combination of hard and stigmatized $\xi$-contractions (of both types) that arise along the iterative integrations by parts of the $\xi$-contraction $C_g^u(\phi, \xi)$.

We now define $O^+_u[C_g^u(\phi, \xi)]$ to stand for the sublinear combination of those $\xi$-contractions that are in the form $(\xi)$.

We then claim (claim 1) that $O^+_u[C_g^u(\phi, \xi)] = (-1)^{\frac{n}{2} - A_1} C_g^u(\phi, \xi)$ (the left hand side here stands for the sublinear combination of complete contractions in the form $C_g^u(\phi, \xi)$ in $O^{Shad}[C_g^u(\phi, \xi)]$). Moreover, we claim (claim 2) that for any other descendant $C_g^d(\phi, \xi)$ of $C_g^u(\phi)$ we will have $O^+_u[C_g^d(\phi, \xi)] = 0$.

The second claim follows by simply observing that $C_g^d(\phi, \xi)$ must contain a factor with an internal contraction, hence each $\xi$-contraction in $O^{Shad}[C_g^u(\phi, \xi)]$ with length $\frac{n}{2} + 1$ must have a factor with an internal contraction. Our first claim follows by integrating by parts all the factors $\xi_i$ that contract against factors $\nabla \phi$ and making all the derivatives $\nabla_i$ hit the factor $\nabla \xi$ and then symmetrizing. We observe that any other $\xi$-contraction that arises in the iterative integration by parts will not be of the form $C_g^u(\phi, \xi)$: It will either have $\xi$-length $\geq \frac{n}{2} + 2$ or a factor $\nabla^a \phi, a \geq 2$ or less than $A_1 - 1$ factors $|\xi|^2$.

In view of the above, and since (50) holds formally, if we replace each expression $S\nabla r_i \ldots r_{A_1} \xi_i \xi_{A_1 + 1} \ldots \nabla^a \phi \xi_1 \ldots \nabla^r \phi \xi_r$ in each complete contraction in (50) by $\nabla^a \phi \nabla^j \phi \xi_1 \ldots \nabla^r \phi \xi_r$ each factor $|\xi|^2$ by a factor $R$, we can then determine $\Sigma_{u \in U^2} a_u C_g^u(\phi)$. Hence, showing (50) would complete the proof of our Lemma.

But (50) is easy to prove: Let us suppose that $C_g^u(\phi)$ is in the form (50) and has less than $A_1 - 1$ factors $R$. It then follows that each descendant $C_g^u(\phi, \xi)$ of $C_g^u(\phi)$ will have less than $A_1 - 1$ factors $|\xi|^2$ (by the Lemma on the acceptable descendants in [2]) and hence, by the iterative integration by parts procedure, each $\xi$-contraction in $Tail^{Shad}[C_g^u(\phi, \xi)]$ will have less than $A_1 - 1$ factors $|\xi|^2$ (by Lemma 15 in [2]) and hence we have shown (50) in this case. Now, we consider the case where $C_g^u(\phi)$ is in the form (50) and has less than $\frac{n}{2} - A_1 - 1$ factors $\Delta \phi$, and hence has at least one factor $\nabla^2 \phi \neq \Delta \phi$. It then follows that each descendant $C_g^u(\phi, \xi)$ of $C_g^u(\phi)$ will have at least one factor $\nabla^2 \phi \neq \Delta \phi$ (by the Lemma on the acceptable descendants in [2]). Hence, we have that each $\xi$-contraction of $\xi$-length $\frac{n}{2} + 1$ in $Tail^{Shad}[C_g^u(\phi)]$ will have at least one factor $\nabla^a \phi, a \geq 2$ and therefore $Tail^{Shad}[C_g^u(\phi)] = 0$.

We are thus left with the case where $u \in U_2 \setminus U^2$ and $C_g^u(\phi)$ has at least $A_1 - 1$ factors $R$ and at least $\frac{n}{2} - A_1 - 1$ factors $\Delta \phi$. It then follows that $C_g^u(\phi)$
must be in the form:

\[
\text{contr}(R^{A_1} \otimes (\Delta \phi) \tilde{\xi}^{1} \otimes |\nabla \phi|^2)
\]

But then, by the iterative integrations by parts procedure, we observe that each \(\tilde{\xi}\)-contraction of \(\tilde{\xi}\)-length \(\frac{p}{2} + 1\) in \(\text{Tail}^{\text{Shad}}[C_{g^n}(\phi)]\) will either have a factor \(\nabla^a \phi, a \geq 2\) or will have two factors \(\nabla \phi\) that contract against each other. Therefore, we again have our desired \((56)\) in this case. We have shown our Lemma.

\(\square\)

**Determining the sublinear combination \(\Sigma_{u \in L^{0,0,A_1}}, \frac{p}{2} - A_1, a_u C_{g^n}^{u}(\phi)\):**

We consider the shadow divergence formula of \(I_{g^n}^{\frac{p}{2} - A_1}(\phi), \text{Shad}[I_{g^n}^{\frac{p}{2} - A_1}(\phi)]\). We focus on the sublinear combination of \(\tilde{\xi}\)-contractions in the form:

\[
\text{contr}((|\tilde{\xi}|^2)^{A_1 - 1} \otimes \nabla_{\xi_1 \ldots \xi_{A_1 - 1}} \tilde{\xi} \otimes \nabla^{ij} \phi \otimes (\nabla)^{1} \phi \otimes \cdots \otimes (\nabla)^{1} \tilde{\xi}^{1} - A_1 - 1 \phi) \quad (57)
\]

We denote the above \(\tilde{\xi}\)-contraction by \(C_{g^n}^{A}(\phi, \tilde{\xi})\) for short. For each \(C_{g^n}(\phi)\) in the form \((44)\) of length \(\frac{p}{2}\), we denote by \(\text{Tail}^{\text{Shad}}[C_{g^n}(\phi)]\) the sublinear combination of \(\tilde{\xi}\)-contractions in the form \((57)\) in \(\text{Tail}^{\text{Shad}}[C_{g^n}(\phi)]\). (Note that we are changing the meaning of \(\text{Tail}^{\text{Shad}}[C_{g^n}(\phi)]\)). This notation extends to linear combinations. Now, since the Shadow divergence formula holds formally, we will have that:

\[
\text{Tail}^{\text{Shad}}[I_{g^n}^{\frac{p}{2} - A_1}(\phi)] = 0
\]

We write out \(I_{g^n}^{\frac{p}{2} - A_1}(\phi)\) in the form:

\[
I_{g^n}^{\frac{p}{2} - A_1}(\phi) = \Sigma_{k \in K} a_k C_{g^n}^{k}(\phi) + \Sigma_{u \in U} a_u C_{g^n}^{u}(\phi) \quad (58)
\]

modulo complete contractions of length \(\geq \frac{p}{2} + 1\). Here \(\Sigma_{k \in K} a_k C_{g^n}^{k}(\phi)\) arises from the sublinear combination \(\Sigma_{A = 0}^{A_1 - 1} \Sigma_{l \in L, \frac{p}{2} - A_1} a_l C(l)\). Hence, we have that \(\Sigma_{k \in K} a_k C_{g^n}^{k}(\phi)\) is known. We note that the index set \(K\) differs from \(K\) in \((43)\). We deduce that:

\[
\Sigma_{k \in K} a_k \text{Tail}^{\text{Shad}}[C_{g^n}^{k}(\phi)] + \Sigma_{u \in U} a_u \text{Tail}^{\text{Shad}}[C_{g^n}^{u}(\phi)] = 0 \quad (59)
\]

Now, we claim that for each \(u \in U \setminus (U^{0,0,A_1,0,\frac{p}{2} - A_1} \cup U^{0,1,A_1,1,\frac{p}{2} - A_1 - 1})\) we have that \(\text{Tail}^{\text{Shad}}[C_{g^n}^{u}(\phi)] = 0\). This follows by a similar reasoning as for the previous case: For each \(u\) above, we have that either \(C_{g^n}^{u}(\phi)\) has less than \(A_1 - 1\) factors \(R\) or it has less than \(\frac{p}{2} - A_1 - 1\) factors \(\Delta \phi\). In the first case we then have that each \(\tilde{\xi}\)-contraction in \(\text{Tail}^{\text{Shad}}[C_{g^n}^{u}(\phi)]\) will have less than \(A_1 - 1\) factors \(|\tilde{\xi}|^2\) and in the second, it will have less than \(\frac{p}{2} - A_1 - 1\) factors \(\nabla \phi\).

In view of this fact, we can then use \((49)\) to determine the sublinear combination \(\Sigma_{u \in L^{0,0,A_1,0,\frac{p}{2} - A_1, a_u \text{Tail}^{\text{Shad}}[C_{g^n}^{u}(\phi)]}}\).
We then claim that knowing $\Sigma_{u \in U^{0,0,A_1,0,\frac{2}{\lambda} - A_1}} a_u\, Tail_{+}^{Shad}[C_{g^n}(\phi)]$ we can determine $\Sigma_{u \in U^{0,0,A_1,0,\frac{2}{\lambda} - A_1}} a_u C_{g^n}(\phi)$. Specifically, we show that for the complete contraction $C_{g^n}^{+}(\phi) = C_{g^n}^{-}(\phi)$, $u \in U^{0,0,A_1,0,\frac{2}{\lambda} - A_1}$, we have that:

$$Tail_{+}^{Shad}[C_{g^n}(\phi)] = (-1)^{\frac{2}{\lambda} - A_1 - 1} 2 A_1 \cdot \left(\frac{n}{2} - A_1\right) \cdot C_{g^n}^{+}(\phi, \tilde{\xi}) \quad (60)$$

**Proof of (60):**

For any $\tilde{\xi}$-contraction $C_{g^n}(\phi, \tilde{\xi})$, we denote by $O_{+}^{Shad}[C_{g^n}(\phi, \tilde{\xi})]$ the sublinear combination in $O_{+}^{Shad}[C_{g^n}(\phi, \tilde{\xi})]$ of $\tilde{\xi}$-contractions in the form (57).

Firstly, we denote by $C_{g^n}^{+}(\phi, \tilde{\xi})$ the descendant of $C_{g^n}^{+}(\phi)$ that arises by replacing each of the $A_1$ factors $R$ by $|\tilde{\xi}|^2$ and each of the $\frac{2}{\lambda} - A_1$ factors $\Delta \phi$ by $\tilde{\xi}^2 \nabla_i \phi$ (in the $N$-cancelled notation). We observe that for any descendant $C_{g^n}^{+}(\phi, \tilde{\xi})$ of $C_{g^n}^{+}(\phi)$ other than the above, we will have that $Tail_{+}^{Shad}[C_{g^n}(\phi, \tilde{\xi})] = 0$. This is true by virtue of the same arguments as for the previous case (at $\tilde{\xi}$-length $\frac{2}{\lambda}$ there must be an internal contraction). Hence, it suffices to show that $O_{+}^{Shad}[C_{g^n}^{+}(\phi, \tilde{\xi})]$ is equal to the right hand side of (60).

So, let us begin by performing the iterative integration by parts. We first integrate by parts the factor $\tilde{\xi}^2$ that contracts against the first factor $\nabla_i \phi$. Note that, although we have imposed restrictions on the order of our integrations by parts, in this case we can pick an order so that we first integrate by parts with respect to this factor $\tilde{\xi}$. If $\nabla_i$ hits a factor $\nabla \phi$ or a factor $\xi$ that does not contract against another factor $\xi$, we denote the $\xi$-contraction that is generically thus obtained by $C_{g^n}^{+}(\phi, \tilde{\xi})$. We observe that $O_{+}^{Shad}[C_{g^n}^{+}(\phi, \tilde{\xi})] = 0$, since each $\xi$-contraction in that sublinear combination will either have length $\geq \frac{n}{2} + 1$ or at least one factor $\nabla^a \phi$, $a \geq 2$. If $\nabla_i$ hits a factor $|\tilde{\xi}|^2$, we obtain an expression $2 \nabla_i |\tilde{\xi}|^2$ and we denote the $\xi$-contraction that we have obtained by $C_{g^n}^{+}(\phi, \tilde{\xi})$. We then proceed to integrate by parts the factor $|\tilde{\xi}|^2$.

Now, if $\nabla^j$ hits a factor $\tilde{\xi}$ that does not contract against another factor $\tilde{\xi}$ or if it hits a factor $|\tilde{\xi}|^2$, we generically denote the $\xi$-contraction that is thus obtained by $C_{g^n}^{+}(\phi, \tilde{\xi})$ and we observe that $O_{+}^{Shad}[C_{g^n}^{+}(\phi, \tilde{\xi})] = 0$. This follows because in the first case we will obtain a $\xi$-contraction of $\tilde{\xi}$-length $\geq \frac{n}{2} + 1$ and in the second we will have less than $A_1 - 1$ factors $|\tilde{\xi}|^2$.

Initially, we consider the $\xi$-contraction $C_{g^n}^{+}(\phi, \tilde{\xi})$ that arises when $\nabla^j$ hits the first factor $\nabla_i \phi$. In that case, $C_{g^n}^{+}(\phi, \tilde{\xi})$ is the complete contraction:

$$\text{contr}((|\tilde{\xi}|^2)^{A_1 - 1} \otimes \nabla^2_i \tilde{\xi} \otimes \nabla^{A_1} \phi \otimes (\nabla)^{r_1} \phi \tilde{\xi} \otimes \cdots \otimes (\nabla)^{r_{\frac{2}{\lambda} - A_1 - 1}} \phi \tilde{\xi} |_{\frac{2}{\lambda} - A_1 - 1}) \quad (61)$$

We show that $O_{+}^{Shad}[C_{g^n}^{+}(\phi, \tilde{\xi})] = (-1)^{\frac{2}{\lambda} - A_1 - 1} C_{g^n}^{+}(\phi, \tilde{\xi})$. 

19
This follows by the iterative integrations by parts procedure. The algorithm to obtain \((-1)^{\frac{n}{2}} - A_1 - 1 C_{g^n}^N(\phi, \xi)\) is to successively integrate by parts each of the \(\frac{n}{2} - A_1 - 1\) factors \(\xi\) that contract against a factor \(\nabla\phi\) and make it hit the one factor \(S\nabla^p\xi\) and then symmetrize. We then obtain \((-1)^{\frac{n}{2}} - A_1 - 1 C_{g^n}^N(\phi, \xi)\). We observe that if at any stage we integrate by parts a factor \(\xi\) and hit the factor \(\nabla^2\phi\) or a factor \(\nabla^2\phi\) or a factor \(\xi\) or a factor \(\nabla\phi\), then performing the rest of the iterative integrations by parts we will not obtain a \(\xi\)-contraction in the form \(C_{g^n}^N(\phi, \xi)\).

On the other hand, we consider the \(\xi\)-contraction that arises when \(\nabla^j\) hits the \(h^{th}\) factor \(\nabla\phi, h \geq 2\). We denote the \(\xi\)-contraction that arises thus by \(C_{g^n}^{h,j}(\phi, \xi)\). We then claim that \(\Sigma_{u \in U}^C \nabla^{a, b}(\phi, \xi)\). It is clear that if we can show the above claim, (60) will follow immediately.

To see this, we initially observe that up to permuting factors \(\nabla\phi\), \(C_{g^n}^{h,j}(\phi, \xi)\) is in the form:

\[
\text{contr}(\|\xi\|^2 A_1 - 1 \otimes \nabla \xi) \otimes (\nabla)^i \phi \otimes (\nabla)^j \nabla^r_1 \phi \xi_{r_1} \otimes \cdots \otimes (\nabla)^r_{A_1 - 1}\nabla\xi_{-A_1 - 1})
\]

(62)

Moreover, it follows that \((-1)^{\frac{n}{2}} - A_1 - 1 C_{g^n}^N(\phi, \xi)\) arises in \(\Omega_{g^n}^{Shad}(C_{g^n}^{h,j}(\phi, \xi))\) when we integrate by parts all the factors \(\xi\), and hit the factor \(S\nabla\xi\) and then replace \(\nabla^{\frac{n}{2}} - A_1 - 1\nabla\xi\) by \(S\nabla^{\frac{n}{2}} - A_1 \xi\). We observe that if we perform any other integration by parts, we will not obtain \(C_{g^n}^N(\phi, \xi)\): If we hit a factor \(\xi^2\) by a \(\nabla\), we will obtain a \(\xi\)-contraction with fewer than \(A_1 - 1\) factors \(\xi^2\). If we hit a factor \(\xi\) that does not contract against another factor \(\xi\), we will have \(\xi\)-length \(\geq \frac{n}{2} + 1\). If we hit a factor \(\nabla\phi\) or the factor \(\nabla^2\phi\), we will respectively have two factors \(S\nabla^p\phi\) with \(p \geq 2\) or one factor \(S\nabla^p\phi\) with \(p \geq 3\). Finally, if we hit the factor \(S\nabla^p\xi\) by a derivative \(\nabla_i\) and anti-symmetrize using the equation:

\[
\nabla_a S\nabla_{r_1 \cdots r_m} \xi_j = S\nabla_{r_1 \cdots r_m} \xi_j + C_{m-1} \cdot S^r \nabla_{r_1 \cdots r_{m-1}} R_{ijkl} \xi^{ij} + \sum_{u \in U} u_{p contr}(\nabla^m R_{abcd} S\nabla^u \xi) \]

(63)

from \cite{2} (and the notational conventions there), we obtain a \(\xi\)-contraction with a factor of the form \(\nabla^m R_{ijkl}\). Hence, by the iterative integrations by parts procedure, the \(O^{\text{Shad}}\) of such a factor will consist of \(\xi\)-contractions with a factor \(\nabla^m R_{ijkl}\), so we have completely shown our claim.

Hence, we have determined \(\Sigma_{u \in U}^C \nabla^{a, b}(\phi, \xi)\). In other words, we have determined the constant \((\text{Const})_{\frac{n}{2}}\) for which:

\[
\Sigma_{a \in U}^C \nabla^{a, b}(\phi, \xi) = (\text{Const})_{\frac{n}{2}} \cdot C_{g^n}^N(\phi, \xi) \]

(64)

Now, we only have to replace each expression \(\|\xi\|^2\) by an expression \(R\) and the expression
\[ \nabla \vec{r}_1^A \cdots \nabla \vec{r}_{A_1-1}^1 \otimes \nabla \phi \otimes (\nabla \phi)^{r_1} \otimes \cdots \otimes (\nabla \phi)^{r_{A_1-1}} \]

by an expression \( R \cdot (\Delta \phi)^{\frac{A_1+1}{2}} \). Then, using (60) and (63), we determine the constant \( Const' \) for which:

\[
\sum_{u \in U^{0.0.,A_1,0}} (\Delta \phi)^{\frac{A_1}{2} - A_1} a_u C_{g^n}^u (\phi) = (Const') \cdot R^{A_1} \cdot (\Delta \phi)^{\frac{A_1}{2} - A_1}
\]

In other words, we determine the sublinear combination \( \sum_{u \in U^{0.0.,A_1,0}} (\Delta \phi)^{\frac{A_1}{2} - A_1} a_u C_{g^n}^u (\phi) \). That concludes the proof of our second claim.

### 4.2 Determining the sublinear combination

\[
\sum_{u \in U^{A_1 - X_1 - C_1, X_1, C_1, A_1 - \Delta_1, \Delta_2}} a_u C_{g^n}^u (\phi).
\]

We call the list \((A_1 - X_1 - C_1, X_1, C_1, A_1 - \Delta_1, \Delta_1)\) the critical list. We denote the index set \( U^{A_1 - X_1 - C_1, X_1, C_1, A_1 - \Delta_1, \Delta_1} \) by \( U^{crit} \) for short. Moreover, whenever we refer to a list \((Z, X, C, \Gamma, \Delta)\) for which we have not yet determined \( \sum_{u \in U^{Z, X, C, \Gamma, \Delta}} a_u C_{g^n}^u (\phi) \), we will say that the list \((Z, X, C, \Gamma, \Delta)\) is subsequent to the critical list. We will also say that \( u \) or \( C_{g^n}^u (\phi) \) is subsequent to the critical list when \( u \in U^{Z, X, C, \Gamma, \Delta} \).

On the other hand, for each list \((Z, X, C, \Gamma, \Delta)\) where we have determined \( \sum_{u \in U^{Z, X, C, \Gamma, \Delta}} a_u C_{g^n}^u (\phi) \), we will say that the list \((Z, X, C, \Gamma, \Delta)\) preceded the critical list. Accordingly, in that case, if \( u \in U^{Z, X, C, \Gamma, \Delta} \), we will say that \( u \) or \( C_{g^n}^u (\phi) \) preceded the critical list.

We will distinguish three cases and separately prove our claim in each of those cases. The first case is when \( \Delta_1 < \frac{A_1}{2} - A_1 \). The second one is when \( \Delta_1 = \frac{A_1}{2} - A_1 \) and \( X_1 > 0 \). The third is when \( \Delta_1 = \frac{A_1}{2} - A_1 \), \( X_1 = 0 \). In the third case we observe that we will have that \( X_1 + C_1 < A_1 \) (otherwise we are in the base case that we have already dealt with). In each of the three cases, we will use the equation:

\[
I_{g^n}^{\frac{A_1}{2}} (\phi) = \sum_{k \in K} a_k C_{g^n}^k (\phi) + \sum_{u \in U^n} a_u C_{g^n}^u (\phi)
\]

which holds modulo complete contractions of length \( \geq \frac{A_1}{2} + 1 \). We recall that the sublinear combination \( \sum_{k \in K} a_k C_{g^n}^k (\phi) \) is known, and each sublinear combination \( U^{Z, X, C, \Gamma, \Delta} \), where \((Z, X, C, \Gamma, \Delta)\) precedes \( U^{crit} \) is also known.

We proceed to prove our claim in each of the three cases.

*The first case.* We consider \( Shad(I_{g^n}^{\frac{A_1}{2}} (\phi)) \) and focus on the sublinear
We denote the sublinear combination of $\xi$-contractions in the form \ref{66} in $\textit{Shad}[g_\alpha^{n A_1}(\phi)]$ by $\textit{Shad}_\alpha[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)]$. We then claim that:

$$\textit{Shad}_\alpha[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)] = 0 \tag{67}$$

This can be seen by the following reasoning: We write out the sublinear combination of $\xi$-contractions of $\xi$-length $\frac{n}{2}$ in $\textit{Shad}[g_\alpha^{n A_1}(\phi)]$ as a linear combination of $\xi$-contractions in the form:

$$\text{contr}(\nabla^{m_1}_{r_1 \ldots r_{m_1}} R_{i_1 j_1 k_1 l_1} \otimes \cdots \otimes \nabla^{m_s}_{s_1 \ldots s_{m_s}} R_{i_s j_s k_s l_s} \otimes \\
\nabla^{p_1}_{t_1 \ldots t_{p_1}} Ric_{\alpha_1 \beta_1} \otimes \cdots \otimes \nabla^{p_q}_{z_1 \ldots z_{p_q}} Ric_{\alpha_q \beta_q} \otimes \nabla^{\nu_1}_{s_1 \ldots s_{\nu_1}} \phi \otimes \cdots \otimes \nabla^{\nu_Z}_{s_{\nu_Z} \ldots s_{\nu_Z}} \phi \tag{68}$$

$$\otimes S\nabla^{\nu_1 \xi_1}_{j_1} \ldots \ldots S\nabla^{\nu_Z \xi_Z}_{j_Z} \otimes |\xi|^2 \otimes \cdots \otimes |\xi|^2)$$

with $Z = \frac{n}{2} - A_1$. Then, we define $\text{Tail}^{\textit{Shad}}[g_\alpha^{n A_1}(\phi)]$ to stand for the sublinear combination in $\text{Tail}^{\textit{Shad}}[g_\alpha^{n A_1}(\phi)]$ that consists of $\xi$-contractions of $\xi$-length $\frac{n}{2}$ for which the decreasing rearrangement of the list $\nu_1, \ldots, \nu_{\frac{n}{2} - A_1}$ is $(\Delta_1 + 2, 2, \ldots, 2, 1, \ldots, 1)$ (we are writing the number $2 \Gamma_1 - 1$ times and $1 \Delta_3$ times. Then, by Lemma \ref{8} we have that:

$$\textit{Shad}_\alpha[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)] = 0 \tag{69}$$

Now, we consider the sublinear combination $\textit{Shad}_{\alpha, \beta}[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)]$ in $\textit{Shad}_\alpha[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)]$ where there are no factors with internal contractions (in particular there are no factors $\nabla^p Ric$ or $\nabla^m R_{ijkl}$ with internal contractions). Then, since the number of internal contractions remains invariant under the permutations of definition 7 in \ref{2}, modulo introducing $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$, we will have that modulo $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$:

$$\textit{Shad}_{\alpha, \beta}[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)] = 0 \tag{70}$$

Moreover, we define $\textit{Shad}_{\alpha, \beta, \gamma}[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)]$ to stand for the sublinear combination in $\textit{Shad}_{\alpha, \beta}[I^{\xi n \rightarrow A_1}_{g_\alpha}(\phi)]$ where the $\Delta_1$ factors $\nabla \phi$ are all contracting against the one factor $\nabla^{\Delta_1 + 2} \phi$. We observe that the number of factors $\nabla \phi$ that contract against the factor $\nabla^{\Delta_1 + 2} \phi$ remains invariant under the permutations.
allowed by definition 7 in [2], modulo introducing $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$. Hence, we have that modulo $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$:

$$Shad_{\alpha, \beta, \gamma}[I_{g^n}^{\frac{n}{2} - A_1}(\phi)] = 0$$  \hfill (71)

Finally, we define $Shad_{\alpha, \beta, \gamma, d}[I_{g^n}^{\frac{n}{2} - A_1}(\phi)]$ to stand for the sublinear combination in $Shad_{\alpha, \beta, \gamma}[I_{g^n}^{\frac{n}{2} - A_1}(\phi)]$ that consists of the $\xi$-contractions with $X_1$ factors $\nabla \xi$ and no more factors of the form $S \nabla^i \xi$ and, in addition, with $C_1$ factors $|\xi|^2$. Since both the number of factors $S \nabla^p \xi$ ($p \geq 1$) and the number of such factors for which $p = 1$, and also the number of factors $|\xi|^2$ is invariant under the permutations of definition 7 in [2], we have that modulo $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$:

$$Shad_{\alpha, \beta, \gamma, d}[I_{g^n}^{\frac{n}{2} - A_1}(\phi)] = 0$$  \hfill (72)

Now, we observe that $Shad_{\alpha, \beta, \gamma, d}[I_{g^n}^{\frac{n}{2} - A_1}(\phi)]$ indeed consists of $\xi$-contractions of the form $[65]$. This follows just because we are considering $\xi$-length $\frac{n}{2}$ and weight $-n$. Hence, we must have $A_1 - X_1 - C_1$ factors $\nabla^m R_{ijkl}$ with no internal contractions. But since the $\xi$-contractions in the form $[66]$ have indeed weight $-n$, it follows that any $\xi$-contraction with the restrictions above and with at least one factor $\nabla^m R_{ijkl}, m > 0$ cannot have weight $-n$.

Now, for each complete contraction $C_{g^n}(\phi)$ in $I_{g^n}^{\frac{n}{2} - A_1}(\phi)$, we denote by $Tail_{\alpha}^{Shad}[C_{g^n}(\phi)]$ the sublinear combination of $\xi$-contractions in the form $[66]$ in $Tail_{\alpha}^{Shad}[C_{g^n}(\phi)]$. This notation extends to linear combinations.

Now, if we write $I_{g^n}^{\frac{n}{2} - A_1}(\phi)$ out as in $[65]$, we claim that for each $C_{g^n}^u(\phi)$, where $u$ is subsequent to the critical list, we have that modulo $\xi$-contractions of $\xi$-length $\geq \frac{n}{2} + 1$:

$$Tail_{\alpha}^{Shad}[C_{g^n}^u(\phi)] = 0$$  \hfill (73)

We will prove this below. For now, we note how we can then determine our desired sublinear combination $\Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi)$. Initially we observe that if we can show $[63]$, we will then be able to determine the sublinear combination $\Sigma_{u \in U^{crit}} a_u Tail_{\alpha}^{Shad}[C_{g^n}^u(\phi)]$ from equation $[67]$. We then also claim that for each $u \in U^{crit}$, the sublinear combination $Tail_{\alpha}^{Shad}[C_{g^n}^u(\phi)]$ is obtained from $C_{g^n}^u(\phi)$ by performing the following algorithm: We replace each factor $R$ by $-|\xi|^2$, each factor $Ric_{ij}$ by $-\nabla_i \xi_j$ and each factor $\Delta \phi$ by $\xi^2 \nabla \phi$ (in $N$-cancelled notation). We then integrate by parts the $\Delta_1$ factors $\xi$ that contract against factors $\nabla \phi$ and make each $\nabla_i$ that arises hit the same factor $\nabla^2 \phi$.

This follows just by the iterative integration by parts procedure, and the same arguments as above. Since we have determined $\Sigma_{u \in U^{crit}} a_u Tail_{\alpha}^{Shad}[C_{g^n}^u(\phi)]$, then by replacing each expression $|\xi|^2$ by $R$, each expression $\xi^2$ by $-Ric_{ij}$ and each expression $\nabla^{\Delta_1 \cdots \Delta_1}$ by $\nabla_{\theta_{\Delta_1}} \cdots \nabla_{\theta_{\Delta_1}} \nabla_{\theta_{-\Delta_1}} \cdots \nabla_{\theta_{-\Delta_1}}$.
\( \cdots \otimes (\nabla)^{s_1} \phi \) by \( (\nabla_{\xi_1}^2 \phi \otimes \cdots \otimes \nabla f^{s_1}_{\phi \otimes \cdots \otimes f} \phi)(\Delta \phi)^{A_1}, \) we have determined the sublinear combination \( \Sigma_{u \in U_{crit}} a_u C^{\mu}_{f,\phi}(\phi). \) Moreover, we see that by construction, the pattern of those particular contractions between indices in factors \( R_{ijkl}, \tilde{R}_{ijkl}, \nabla^2 \phi \) is preserved.

So, matters are reduced to showing that for each \( C^{\mu}_{f,\phi}(\phi) \) where \( u \) is subsequent to the critical character, we must have that \( \text{Tail}^{Shad}_{\phi}[C^{\mu}_{f,\phi}(\phi)] = 0. \) Firstly, we observe that we may restrict attention to the descendants of \( C^{\mu}_{f,\phi}(\phi) \) that do not have internal contractions. This follows by the same reasoning as in the previous case. Then, we observe that if \( C^{\mu}_{f,\phi}(\phi) \) has \( \Delta < A_1 \) factors \( \Delta \phi, \) then each \( \xi \)-contraction of length \( \frac{1}{2} \) in \( \text{Tail}^{Shad}_{\phi}[C^{\mu}_{f,\phi}(\phi)] \) will have less than \( A_1 \) factors \( \nabla \phi. \) Similarly, if \( C^{\mu}_{f,\phi}(\phi) \) has less than \( C_1 \) factors \( R \) then each complete \( \xi \)-contraction of \( \xi \)-length \( \frac{1}{2} \) in \( \text{Tail}^{Shad}_{\phi}[C^{\mu}_{f,\phi}(\phi)] \) will have less than \( C_1 \) expressions \( |\xi|^2. \) Finally, if \( C^{\mu}_{f,\phi}(\phi) \) has \( A_1 \) factors \( \Delta \phi, C_1 \) factors \( R \) and less than \( X_1 \) factors \( \tilde{R}_{ijkl} \), then each \( \xi \)-contraction in \( \text{Tail}^{Shad}_{\phi}[C^{\mu}_{f,\phi}(\phi)] \) will either have less than \( X_1 \) factors \( \nabla_i \xi \) or less than \( C_1 \) expressions \( |\xi|^2. \) Thus we have shown our claim.

**The second case,** where \( \Delta_1 = \frac{n}{2} - A_1 \) and \( X_1 > 0. \) We again consider the shadow divergence formula for \( I_{g}^{\frac{n}{2} - A_1}(\phi), \) and we focus on the sublinear combination of \( \xi \)-contractions in the form:

\[
\begin{align*}
\text{contr}(R_{i_1,1,1 l_1} & \otimes \cdots \otimes R_{i_1 \otimes \cdots \otimes f_{\frac{n}{2} - A_1}(\phi)} \otimes \nabla_{a_1} \xi_{a_1} \otimes \cdots \otimes \nabla_{a_2} \xi_{a_2} \otimes \cdots \otimes \nabla_{a_X} \xi_{a_X} ((|\xi|^2)^{C_1} \otimes (\nabla)^{s_1} \phi \otimes \cdots \otimes (\nabla)^{s_A_1 \phi}) \\
\text{Shad}_{\phi} [I_{g}^{\frac{n}{2} - A_1}(\phi)] = 0 \quad (75)
\end{align*}
\]

We denote the above sublinear combination by \( \text{Shad}_{\phi} [I_{g}^{\frac{n}{2} - A_1}(\phi)]. \) Since the shadow divergence formula holds formally, by an analogous argument as for the previous case, it follows that:

\[
\text{Shad}_{\phi} [I_{g}^{\frac{n}{2} - A_1}(\phi)] = 0
\]

For each complete contraction \( C_{g,\phi}^{\mu}(\phi) \) in \( I_{g}^{\frac{n}{2} - A_1}(\phi), \) we denote by \( \text{Tail}^{Shad}_{\phi}[C_{g,\phi}^{\mu}(\phi)] \) the sublinear combination of \( \xi \)-contractions in the form \( (74) \) in \( \text{Tail}^{Shad}_{\phi}[C_{g,\phi}^{\mu}(\phi)]. \) (This is not the same as the previous \( \text{Tail}^{Shad}_{\phi}[C_{g,\phi}^{\mu}(\phi)]. \))

Now, by a similar reasoning as for the previous case, we observe that for each \( C_{g,\phi}^{\mu}(\phi) \) that is subsequent to the critical character we have \( \text{Tail}^{Shad}_{\phi}[C_{g,\phi}^{\mu}(\phi)] = 0. \) This follows because if \( C_{g,\phi}^{\mu}(\phi) \) has either less than \( A_1 \) factors \( \Delta \phi, \) or \( A_1 \) such factors and less than \( C_1 \) factors \( R \) or \( C_1 \) such factors and less than \( X_1 \) factors \( \tilde{R}_{ijkl}. \) In those cases, we respectively have that each \( \xi \)-contraction in \( \text{Tail}[C_{g,\phi}^{\mu}(\phi)] \) will have less than \( A_1 \) factors \( \nabla \phi \) or less than \( C_1 \) factors \( |\xi|^2 \) or less than \( X_1 \) factors \( S \nabla^s \xi. \) Hence, using \( (75), \) we determine the sublinear com-
contractions $\Sigma_{u \in U^{crit}} a_u Tail_\phi^Shad[C_{g^n}^u(\phi)]$.

We now claim that for each $C_{g^n}^u(\phi), u \in U^{crit}$, the sublinear combination $Tail_\phi^Shad[C_{g^n}^u(\phi)]$ arises as follows: We initially replace each of the $C_1$ factors $R$ by $|\xi|^2$, each of the $X_1$ factors $Ric_{ij}$ by $-\nabla_i\xi_j$ and each of the $\frac{2}{n} - A_1$ factors $\nabla^i\phi\xi^i$ (we are using $N$-cancelled notation). We then integrate by parts the $\frac{2}{n} - A_1$ factors $\xi$ that contract against a factor $\nabla\phi$ and make the derivatives $\nabla^i$ hit the same one factor $\nabla_i\xi_j$ and replace $\nabla_{i_1\ldots i_{2-A_1}}\nabla_i\xi_j$ by $S\nabla_{i_1\ldots i_{2-A_1}}\xi_j$. This follows by the iterative integrations by parts procedure, as in the previous case.

Therefore, once we have determined $\Sigma_{u \in U^{crit}} a_u Tail_\phi^Shad[C_{g^n}^u(\phi)]$, we can determine $\Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi)$ as follows: We replace each factor $|\xi|^2$ by $R$, each factor $\nabla_i\xi_j$ by $-Ric_{ij}$ and each expression $S\nabla_{i_1\ldots i_{2-A_1}}\xi_j$ by $Ric_{a_1b_1}(\Delta \phi)^{2-A_1}$. We then determine the sublinear combination $\Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi)$.

**The third case.**

Finally, we have to consider the third case. We now consider $I_{g^n}^{2-A_1}(\phi)$ and distinguish the two subcases $C_1 = 0$ or $C_1 > 0$.

**The first subcase** $C_1 = 0$. Modulo complete contractions of length $\geq \frac{2}{n} + 1$, we write out $I_{g^n}^{2}(\phi)$ in the form:

$$I_{g^n}^{2}(\phi) = \Sigma_{g \in G} a_g C_{g^n}^g(\phi) + \Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi) + \Sigma_{u \in U^{subs}} a_u C_{g^n}^u(\phi) \quad (76)$$

where $\Sigma_{g \in G} a_g C_{g^n}^g(\phi)$ stands for the known sublinear combination in $I_{g^n}^{2}(\phi)$ (this now includes a part of $\Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi)$). $\Sigma_{u \in U^{crit}} a_u C_{g^n}^u(\phi)$ stands for the sublinear combination of complete contractions indexed in the critical list, $U^{crit}$. Finally, $\Sigma_{u \in U^{subs}} a_u C_{g^n}^u(\phi)$ stands for the sublinear combination of complete contractions $C_{g^n}^u(\phi)$ that are subsequent to the critical list.

We focus on the super divergence formula for $I_{g^n}^{2}(\phi)$. We pick out the sublinear combination of complete contractions in the form:

$$\text{contr}(\nabla^{A_1}_{i_1\ldots i_{2-A_1}} R_{i_1j_1k_1l_1} \otimes R_{i_2j_2k_2l_2} \otimes \cdots \otimes R_{i_{2-A_1}j_{2-A_1}k_{2-A_1}l_{2-A_1}} \otimes (\nabla)^{s_1} \phi \otimes \cdots \otimes (\nabla)^{s_{2-A_1}} \phi) \quad (77)$$

where each of the factors $\nabla\phi$ contracts against an index in the factor $\nabla^{A_1} R_{ijkl}$.

We denote the corresponding sublinear combination of complete contractions in $\text{supdiv}_+ I_{g^n}^{2-A_1}(\phi)$ by $\text{supdiv}_+ I_{g^n}^{2-A_1}(\phi)$. Since the super divergence formula holds formally, it follows that:

$$\text{supdiv}_+ I_{g^n}^{2-A_1}(\phi) = 0$$
modulo complete contractions of length $\geq \frac{n}{2} + 1$. Now, for each $C_g^n(\phi)$ in $I_{\frac{n}{2}}^{-A_1}C_{g,n}(\phi)$, we denote by $Tail_+[C_g^n(\phi)]$ the sublinear combination in $Tail[C_g^n(\phi)]$ that consists of complete contractions in the form (77).

We then again observe that for each $u$ that is subsequent to the critical list, we have $Tail_+[C_g^n(\phi)] = 0$. This follows since if $C_g^n(\phi)$ is subsequent to the critical list it must have less than $\frac{n}{2} - A_1$ factors $\Delta \phi$, hence any complete contraction of length $\frac{n}{2}$ in $Tail_C^n(\phi)$ must have less than $\frac{n}{2} - A_1$ factors $\nabla \phi$. On the other hand, for each $u \in U_{crit}$ we have that $Tail_+[C_g^n(\phi)]$ arises from $C_g^n(\phi)$ as follows: We replace each of the factors $\Delta \phi$ by $\nabla_i \phi^i \xi^j$ and then integrate by parts the $\frac{n}{2} - A_1$ factors $\xi^j$ and make each of them hit the same factor $R_{ijkl}$ (there are $A_1$ choices of the factor $R_{ijkl}$ that we may pick). The sublinear combination that arises thus is $Tail_+[C_g^n(\phi)]$. In fact, we observe that if $C_g^n(\phi)$ is of the form:

$$contr(R_{i_1 j_1 k_1 l_1} \cdots R_{i_4 A_1 k A_1 l A_1} \otimes (\Delta \phi)^{\frac{n}{2} - A_1})$$

(78)

Then $Tail_+[C_g^n(\phi)]$ can be written as a sum of $A_1$ complete contractions in the form:

$$(-1)^{\frac{n}{2} - A_1} contr(\nabla_{i_1 \cdots i_{\frac{n}{2} - A_1}} R_{ijkl} \otimes \cdots \otimes R_{i' j' k' l'} \otimes (\nabla)^{i_1} \phi \otimes \cdots \otimes (\nabla)^{i_{\frac{n}{2} - A_1}} \phi)$$

(79)

where the $h^{th}$ term in the sum arises from $C_g^n(\phi)$ by replacing all the factors $\Delta \phi$ by a factor $\nabla_{i_h} \phi$ ($1 \leq j \leq \frac{n}{2} - A_1$) and then hitting the $h^{th}$ factor $R_{ijkl}$ in $C_g^n(\phi)$ by $\frac{n}{2} - A_1$ derivatives $(\nabla)^{i_h}$. In order to facilitate our work further down, we will write out:

$$Tail_+[C_g^n(\phi)] = \Sigma_{h=1}^{A_1} C^{n,h}_{g^n}(\phi)$$

(80)

where $C^{n,h}_{g^n}(\phi)$ stands for the $h^{th}$ complete contraction explained above. Given the form (78) of $C_g^n(\phi)$, we have that $C^{n,h}_{g^n}(\phi)$ will be in the form:

$$contr(R_{i_1 j_1 k_1 l_1} \cdots \nabla_{i_4 A_1 k A_1 l A_1} \otimes (\nabla)^{i_1} \phi \otimes \cdots \otimes (\nabla)^{i_{A_1}} \phi)$$

(81)

Now, for each $u \in U_{crit}$, we denote by $C_u(g^n)$ the complete contraction of weight $-2A_1$:

$$contr(R_{i_1 j_1 k_1 l_1} \cdots R_{i_4 A_1 k A_1 l A_1})$$

We then claim that we can determine the linear combination $\Sigma_{u \in U_{crit}} a_u C_u(g^n)$. Given the form (78) of each $C_g^n(\phi)$, $u \in U_{crit}$, that would then imply that we can determine the sublinear combination $\Sigma_{u \in U_{crit}} a_u C_{g^n}(\phi)$, and the proof of our third case for the subcase $C_1 = 0$ would be complete. In order to determine $\Sigma_{u \in U_{crit}} a_u C_u(g^n)$, we do the following:
We may re-express $\supdiv_+ \left[ T^{\frac{n}{2}} - A_1(\phi) \right]$ in the form:
\[
\Sigma_{u \in U^{crit}} a_u Tail_+ [C^u_{g^n}(\phi)] + \Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi)] = 0 \quad \text{(82)}
\]
modulo complete contractions of length $\geq \frac{n}{2} + 1$. Here each $Tail_+ [C^g_{g^n}(\phi)]$ consists of complete contractions in the form (77) and since the sublinear combination $\Sigma_{g \in G} a_g C^g_{g^n}(\phi)$ is known, we have that the sublinear combination $\Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi)]$ is known. Alternatively, in our new notation using (80):
\[
\Sigma_{u \in U^{crit}} a_u \Sigma_{h=1}^A C^u_{g^n}(\phi) + \Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi)] = 0 \quad \text{(83)}
\]
modulo complete contractions of length $\geq \frac{n}{2} + 1$. We will then determine the sublinear combination $\Sigma_{u \in U^{crit}} a_u C^u(g^n)$ by a trick:

Initially, we polarize the $\frac{n}{2} - A_1$ functions $\phi$ in the above equation. We denote by $C^u_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})$ the complete contraction:
\[
\text{contr}(R_{i_1,j_1,k_1,l_1} \otimes \cdots \otimes R_{i_1,j_1,k_1,l_1} \otimes (\nabla)^{i_1 \Delta_1} \phi_1 \otimes \cdots \otimes (\nabla)^{i_{\Delta_1} \Delta_1} \phi_{\Delta_1})
\]
(84)

We also denote by $\Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})]$ the sublinear combination of complete contractions that arises from $\Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi)]$ by polarizing the $\Delta_1$ functions $\phi$. It will be a linear combination of complete contractions in the form:
\[
\text{contr}(\nabla^{\Delta_1}_{i_1 \cdots l_1} R_{i_1,j_1,k_1,l_1} \otimes \cdots \otimes R_{i_1,j_1,k_1,l_1} \otimes (\nabla)^{i_1 \Delta_1} \phi_1 \otimes \cdots \otimes (\nabla)^{i_{\Delta_1} \Delta_1} \phi_{\Delta_1})
\]
(85)
where each $\nabla \phi_h$ contracts against the same factor $\nabla^{\Delta_1}_{i_1 \cdots l_1} R_{i_1,j_1,k_1,l_1}$. Again, since $\Sigma_{g \in G} a_g C^g_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})$ arises from $\Sigma_{g \in G} a_g C^g_{g^n}(\phi)$ by polarization, we have that the sublinear combination $\Sigma_{g \in G} a_g C^g_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})$ is known. Therefore, from (83) we derive an equation modulo complete contractions of length $\geq \frac{n}{2} + 1$:
\[
\Sigma_{u \in U^{crit}} a_u \Sigma_{h=1}^A C^u_{g^n}(\phi_1, \ldots, \phi_{\Delta_1}) + \Sigma_{g \in G} a_g Tail_+ [C^g_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})] = 0 \quad \text{(86)}
\]

**Definition 1** For each $0 \leq \kappa \leq \Delta_1$, we define $C^u_{g^n}(\phi_{\kappa+1}, \ldots, \phi_{\Delta_1})$ to stand for the complete contraction:
\[
\text{contr}(R_{i_1,j_1,k_1,l_1} \otimes \cdots \otimes R_{i_1,j_1,k_1,l_1} \otimes (\nabla)^{i_{\kappa+1} \Delta_1} \phi_{\kappa+1} \otimes \cdots \otimes (\nabla)^{i_{\Delta_1} \Delta_1} \phi_{\Delta_1})
\]
(87)

It arises from $C^u_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})$ by erasing the factors $\nabla \phi_h, h \leq \kappa$ and also erasing the indices that they contract against in the factor $\nabla^{\Delta_1}_{i_1 \cdots l_1} R_{i_1,j_1,k_1,l_1}$. We observe that for $\kappa = 0$, our notation is consistent. We also have for $\kappa + 1 = \Delta_1$, we obtain $C^u(g^n)$. We note that by construction $C^u_{g^n}(\phi_1, \ldots, \phi_{\Delta_1})$ has length $\frac{n}{2} - \kappa$. 
We claim that for any combination of complete contractions in the form (88).

\[
\text{contr}(\nabla^{\Delta_{-\kappa}} R_{i_{1}j_{1}k_{1}l_{1}} \otimes R_{i_{2}j_{2}k_{2}l_{2}} \otimes \cdots \otimes R_{i_{n}j_{n}k_{n}l_{n}} \otimes (\nabla)^{i_{k+1}} \phi_{\Delta_{1}} \otimes \cdots \otimes (\nabla)^{j_{\Delta_{1}-\kappa}} \phi_{\Delta_{1}})
\]

(88)

where each of the factors \(\nabla \phi_{h}\) contracts against an index in the factor \(\nabla^{\Delta_{1}-\kappa} R_{ijkl}\).

We observe that up to switching the position of the factor \(\nabla^{\Delta_{1}-\kappa-1} R_{ijkl}\) and a factor \(R_{R^{'},j^{'},k^{'},l^{'}}\), the complete contractions \(C^{u,h}_{g} (\phi_{\kappa+1}, \ldots, \phi_{\Delta_{1}})\) are in the form \(SS\) above.

We now let \(\Sigma_{g \in G^{n}} a_{g} C^{g}_{g}(\phi_{\kappa+1}, \ldots, \phi_{\Delta_{1}})\) stand for a generic known linear combination of complete contractions in the form \(SS\).

Our claim is then the following:

**Lemma 7** We claim that for any \(\kappa, 0 \leq \kappa \leq \Delta_{1}\), we will have that modulo complete contractions of length \(\geq \frac{\Delta}{2} - \kappa + 1\):

\[
\Sigma_{u \in U^{crit}} a_{u} \Sigma_{h=1}^{A_{n}} C^{u,h}_{g}(\phi_{\kappa+1}, \ldots, \phi_{\Delta_{1}}) + \Sigma_{g \in G^{n}} a_{g} C^{g}_{g}(\phi_{\kappa+1}, \ldots, \phi_{\Delta_{1}}) = 0
\]

(89)

Clearly if we can show the above, then using the case \(\kappa = \Delta_{1}\), we will then have shown our third case above in the first subcase. The equation holds exactly because terms of greater length have the wrong weight.

**Proof:** We will prove the above by an induction. We assume that we know our Lemma for \(\kappa = k\) and we will show it for \(\kappa = k+1\), where \(k \leq \Delta_{1}\).

We write out our inductive hypothesis:

\[
L^{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}}) = \Sigma_{u \in U^{crit}} a_{u} \Sigma_{h=1}^{A_{n}} C^{u,h}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}}) + \Sigma_{g \in G^{n}} a_{g} C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})
\]

(90)

where each \(C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})\) has length \(\geq \frac{\Delta}{2} - k + 1\).

For each complete contraction \(C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})\) of weight \(-n + 2k\) we define, for the purposes of this proof:

\[
\text{Image}_{\phi^{'}_{g}}(C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})) = \partial_{\lambda} |_{\lambda=0} [e^{\lambda(n-2k)}] C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})
\]

(91)

Now, by our inductive hypothesis, we deduce that:

\[
\text{Image}_{\phi^{'}_{g}}(\Sigma_{u \in U^{crit}} a_{u} \Sigma_{h=1}^{A_{n}} C^{u,h}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})) + \text{Image}_{\phi^{'}_{g}}(\Sigma_{g \in G^{n}} a_{g} C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}})) = \text{Image}_{\phi^{'}_{g}}(\Sigma_{g \in G^{n}} a_{g} C^{g}_{g}(\phi_{k+1}, \ldots, \phi_{\Delta_{1}}))
\]

(92)
Homogeneity of that arises either by virtue of the transformation law (29) or by virtue of the contractions that arises from $\nabla g$ when we replace the critical factor by an expression stand for the sublinear combination that arises in each contraction. We make a note on how the operation $T_{ijkl} = g_{ij} g_{kl}$ is determined as follows: We arbitrarily pick out one factor $T_{g^m}$ in $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ and we make all its indices free. We thus have a tensor $T_{ijkl}$. Then, consider all the terms in $T_{ijkl}'$ that are linear in $\phi'$ and involve at least one derivative of $\phi'$. We arbitrarily replace $T_{g^m}$ in $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ by one of these terms, we leave all the other factors unaltered, and perform the same particular contractions as for $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$. Adding over all these arbitrary substitutions, we obtain $\text{Image}_1' \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$.

Now, we restrict our attention to complete contractions $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ in the form $\Delta_1$ and we wish to understand which complete contractions in $\text{Image}_1' \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ are in the form:

$$\text{contr}(\nabla^{\Delta_1 - k - 1} R_{i_1 j_1 k_1 l_1} \otimes R_{i_2 j_2 k_2 l_2} \otimes R_{i_3 A_1 j_3 A_1 k_3 A_1 l_3 A_1} \otimes \nabla \nabla \phi_{k+2} \otimes \nabla \phi_{\Delta_1} \otimes \cdots \otimes (\nabla)^h \phi' \otimes \nabla_h \phi_{k+1})$$

(93)

In the above complete contraction, the length is $\frac{n}{2} - k + 1$ and each of the factors $\nabla \phi_h, h \geq k + 2$ contracts against the factor $\nabla^{\Delta_1 - k - 1} R_{ijkl}$ and the two factors $\nabla \phi_{k+1}, \nabla \phi'$ contract between themselves. We will call such contractions targets. We denote their sublinear combination in each $\text{Image}_1' \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ by $\text{Image}_1' \phi' \eta [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$.

Now, let us further analyze each $\text{Image}_1' \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$, where $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ is in the form $\Delta_1$. For each factor $T_j = \nabla^m R_{ijkl}$ ($m \geq 0, 1 \leq f \leq A_1$), we denote by $\text{Full} \phi' T_j [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ the sum of four complete contractions that arises from $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ by replacing the factor $T_j = \nabla^m R_{ijkl}$ by one of the linear expressions $\nabla^m \nabla^2 \phi' \otimes \nabla$ on the right hand side of (93) and then adding those four substitutions. It follows that each $\text{Full} \phi' T_j [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ is a sum of four complete contractions of length $\frac{n}{2} - k - 1$, each in the form:

$$\text{contr}(\nabla^m \nabla^{\Delta_1 - 1} R_{i j k l} \otimes \cdots \otimes \nabla^m \nabla^{\Delta_1} \otimes \nabla' \phi' \otimes \nabla \phi_{k+1} \otimes \cdots \otimes \nabla \phi_{\Delta_1})$$

(94)

where $r \geq 2$, and each $m_u \geq 0$. This follows from the transformation law (28).

On the other hand, for each $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$, we make note of the one factor $\nabla^m R_{ijkl}$ with $m > 0$ and we call it critical. We let $\text{LC} \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ stand for the sublinear combination that arises in $\text{Image}_1' \phi' [C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})]$ when we replace the critical factor by an expression $\nabla^m R_{ijkl} \nabla^m \phi'$ or $\nabla^m R_{ijkl} \nabla^m \phi' \otimes \nabla^m \phi' \otimes \nabla^m \phi'$. That arises either by virtue of the transformation law (28) or by virtue of the homogeneity of $R_{ijkl}$ (see (28)).

Then, for each complete contraction $C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_1})$ on the left hand
side of (92) we have:

\[
\text{Image}^1_{g^n}[C_g^n(\phi_{k+1}, \ldots, \phi_{\Delta_1})] = \sum_{f=1}^{A_1} \text{Full}_{T_f}[C_g^n(\phi_{k+1}, \ldots, \phi_{\Delta_1})] + LC^{crit}_{g^n}[C_g^n(\phi_{k+1}, \ldots, \phi_{\Delta_1})] \tag{95}
\]

We will now show that:

\[
\sum_{u \in \mathcal{U}^{crit}} a_u \sum_{f=1}^{A_1} \text{Full}_{T_f}[C_{g^{u,h}}(\phi_{k+1}, \ldots, \phi_{\Delta_1})] + \\
\sum_{g \in G} a_g \sum_{f=1}^{A_1} \text{Full}_{T_f}[C_{g^n}(\phi_{k+2}, \ldots, \phi_{\Delta_1})] = \sum_{j \in \mathcal{J}} a_j C_{g^n}^j(\phi_{k+1}, \ldots, \phi_{\Delta_1}, \phi') \tag{96}
\]

where each \(\sum_{j \in \mathcal{J}} a_j C_{g^n}^j(\phi_{k+1}, \ldots, \phi_{\Delta_1}, \phi')\) has length \(\geq \frac{n^2}{2} - k + 1\) and is not a target.

We see this as follows: Initially, we recall equation (92), where the left hand side can be explicitly written out by virtue of (95) and the right hand side consists of complete contractions of length \(\geq \frac{n^2}{2} - k + 1\). This follows from \(28\) and \(29\). Therefore, recalling that each \(LC^{crit}_{g^n}[C_g^n(\phi_{k+1}, \ldots, \phi_{\Delta_1})]\) in (95) consists of complete contractions of length \(\frac{n^2}{2} - k + 1\), we have:

\[
\sum_{u \in \mathcal{U}^{crit}} a_u \sum_{h=1}^{A_1} \sum_{f=1}^{A_1} \text{Full}_{T_f}[C_{g^{u,h}}(\phi_{k+1}, \ldots, \phi_{\Delta_1})] + \\
\sum_{g \in G} a_g \sum_{f=1}^{A_1} \text{Full}_{T_f}[C_{g^n}(\phi_{k+2}, \ldots, \phi_{\Delta_1})] = 0 \tag{97}
\]

modulo complete contractions of length \(\geq \frac{n^2}{2} - k + 1\).

Now, the above holds formally. Hence, there is a sequence of permutations among the indices of the factors in the left hand side of the above with which we can make the left hand side of the above formally zero, modulo introducing complete contractions of length \(\geq \frac{n^2}{2} - k + 1\). We want to keep track of the correction terms that arise. We see that the correction terms can only arise by applying the identity \([\nabla A \nabla B - \nabla B \nabla A]X_C = R_{ABCD}X_D\). But we see that if we apply this identity to a factor \(\nabla^u R_{ijkl}\), we introduce a correction term of length \(\frac{n^2}{2} - k + 1\) which will have a factor \(\nabla^r \phi', r \geq 2\). This is true because each expression consists of complete contractions in the form (94), so there is such a factor to begin with. Hence, we do not obtain a target in this way. On the other hand, if we apply the identity \([\nabla A \nabla B - \nabla B \nabla A]X_C = R_{ABCD}X_D\) to the factor \(\nabla^r \phi', r \geq 2\), we will obtain a correction term which will either have a factor \(\nabla^u \phi', u \geq 2\) or a factor \(\nabla \phi'\) which contracts against a factor \(\nabla^t R_{ijkl}\). Therefore, we do not obtain a targets in this way either. We have shown (96).

Our next claim is:
Claim A: For each \( u \in U^{\text{crit}} \), \( 1 \leq h \leq A_1 \):

\[
LC_{\text{crit}}[C_{g^n}^{u,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] = \]
\[
( -2 - (\Delta_1 - k - 1)) C_{g^n}^{u,h}(\phi_{k+2}, \ldots, \phi_{\Delta_i})(\nabla)^h \phi' \nabla_h \phi_{k+1} \tag{98} \]
\[
+ \sum_{j \in J} a_j C_{g^n}^{2,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i})
\]

where the linear combination \( \sum_{j \in J} a_j C_{g^n}^{2,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i}, \phi') \) is a generic linear combination of complete contractions of length \( \frac{k}{2} - k + 1 \) that are not targets.

We show claim A as follows: For each complete contraction \( C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i}) \) appearing on the left hand side of (90), we have defined \( LC_{\text{crit}}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \).

Now, we pay special attention to the one index \( i_{k+1} \) in the critical factor that is contracting against the factor \( \nabla \phi_{k+1} \). Let \( LC_{\text{crit},a}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) be the sublinear combination that arises in \( LC_{\text{crit}}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) when we replace the critical factor \( \nabla^{m-k} \phi_{\Delta_i} \) by an expression \( \nabla^{m-k}_{r_{k+1} \ldots r_m} R_{ijkl} \).

(Note that the index \( r_{k+1} \) is the one that contracted against the factor \( \nabla \phi_{k+1} \) in \( C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i}) \)). We denote by \( LC_{\text{crit},b}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) the sublinear combination that arises in \( LC_{\text{crit}}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) when we replace the critical factor in any other way.

Hence, \( LC_{\text{crit},a}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) arises by replacing the critical factor by an expression in either the form \( \nabla^h \phi' \nabla^u R_{ijkl} \), \( \nabla^h \phi' \nabla^u R_{ijkl} g_{ab} \) with \( h \geq 2 \) or of the form \( \nabla^\alpha \phi' \nabla^u R_{ijkl} \), \( \nabla^\alpha \phi' \nabla^u R_{ijkl} g_{ab} \) where the index \( \alpha \) is not the index \( r_{k+1} \) that contracts against \( \nabla \phi_{k+1} \).

We observe that the sublinear combinations \( LC_{\text{crit},a}[C_{g^n}^{u,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \), \( LC_{\text{crit},b}[C_{g^n}^{u,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) consist of targets, whereas the sublinear combinations \( LC_{\text{crit},b}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \), \( LC_{\text{crit},a}[C_{g^n}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] \) contain no targets.

Therefore, in view of the above, in order to show Claim A, we only have to show that for each \( u \in U^{\text{crit}} \) and each \( 1 \leq h \leq A_1 \), we have that:

\[
LC_{\text{crit},a}[C_{g^n}^{u,h}(\phi_{k+1}, \ldots, \phi_{\Delta_i})] = \]
\[
( -2 - (\Delta_1 - k - 1)) C_{g^n}^{u,h}(\phi_{k+2}, \ldots, \phi_{\Delta_i})(\nabla)^h \phi_1 \nabla_h \phi' \tag{99} \]

Hence, we only have to show that the sublinear combination of expressions in \( \text{Image} \phi' [\nabla^{\Delta_1-k}_{r_{k+1} \ldots r_{\Delta_i}} R_{ijkl}] \) that are in the form \( \nabla_{r_{k+1} \ldots r_{\Delta_i}} \phi' \nabla^{\Delta_1-k}_{r_{k+2} \ldots r_{\Delta_i}} R_{ijkl} \) is precisely \( ( -2 - (\Delta_1 - k - 1)) \cdot \nabla_{r_{k+1} \ldots r_{\Delta_i}} \phi' \nabla^{\Delta_1-k}_{r_{k+2} \ldots r_{\Delta_i}} R_{ijkl} \). But this is only a matter of applying \( \nabla^{\Delta_1-k}_{r_{k+1} \ldots r_{\Delta_i}} R_{ijkl} \) to all the pairs \( (r_{k+1}, r_a) \), \( a \geq k + 2 \) and the pairs \( (r_{k+1}, i), \ldots (r_{k+1}, l) \) and also by taking into account the expression
\( 2 \nabla_{r_{k+1} \ldots r_{\Delta_i}} \phi' \nabla^{\Delta_1-k-1}_{r_{k+2} \ldots r_{\Delta_i}} R_{ijkl} \) that arises by virtue of the homogeneity of the factor \( R_{ijkl} \).
Combining the equations (92), (95), (96), (98) and (99) above, we have that:

\[
\sum_{j} a_j C^i_{g^n}(\phi_{k+1}, \ldots, \phi_1, \phi') + \sum_{u \in \mathcal{U}} a_u \sum_{h=1}^{A_1} LC^{crit, \alpha}_{g^n} [C^u_{g^n} (\phi_{k+1}, \ldots, \phi_1)] \\
+ \sum_{g \in \mathcal{G}} a_g LC^{crit, \alpha}_{g^n} [C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1)] + \sum_{u \in \mathcal{U}} a_u \sum_{h=1}^{A_1} LC^{crit, \beta}_{g^n} [C^u_{g^n} (\phi_{k+1}, \ldots, \phi_1)] \\
+ \sum_{g \in \mathcal{G}} a_g LC^{crit, \beta}_{g^n} [C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1)] = \sum_{z \in Z} a_z C^z_{g^n} (\phi_{k+1}, \ldots, \phi_1, \phi')
\]

(100)

where the sublinear combination \( \sum_{z \in Z} a_z C^z_{g^n} (\phi_{k+1}, \ldots, \phi_1, \phi') \) stands for:

\[
\text{Image}_1^{\phi'} [\sum_{g \in \mathcal{G}} a_g C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1)]]
\]

and hence each \( C^z_{g^n} (\phi_{k+1}, \ldots, \phi_1, \phi') \) either has length \( \geq \frac{n}{2} - \kappa + 2 \) or has length \( \geq \frac{n}{2} - k + 1 \) but has a factor \( \nabla^u \phi', u \geq 2 \) (so it is not a target). Therefore, since (100) must hold formally, we deduce that, modulo complete contractions of length \( \geq \frac{n}{2} - k + 2 \):

\[
\sum_{u \in \mathcal{U}} a_u \sum_{h=1}^{A_1} LC^{crit, \alpha}_{g^n} [C^u_{g^n} (\phi_{k+1}, \ldots, \phi_1)] \\
+ \sum_{g \in \mathcal{G}} a_g LC^{crit, \alpha}_{g^n} [C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1)] = 0
\]

(101)

Now, since we are assuming that the linear combination \( \sum_{g \in \mathcal{G}} a_g C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1) \) is known, we deduce that the linear combination \( \sum_{g \in \mathcal{G}} a_g LC^{crit, \alpha}_{g^n} [C^g_{g^n} (\phi_{k+1}, \ldots, \phi_1)] \) is also known.

We have thus completed the proof of the third case if \( C_1 = 0 \). \( \square \)

The subcase \( C_1 > 0 \):

The second subcase is almost entirely similar. We again write out \( I_{g^n}^{\tilde{\phi}} (\phi) \) in the form (76). We write \( C_1 = \gamma \). We consider the Shadow divergence formula for \( I_{g^n}^{\tilde{\phi} - A_1} (\phi) \) and we focus on the sublinear combination \( \text{Shad}_{\tilde{\phi}} [I_{g^n}^{\tilde{\phi} - A_1} (\phi)] \) in \( \text{Shad}[I_{g^n}^{\tilde{\phi} - A_1} (\phi)] \) which consists of \( \tilde{\xi} \)-contractions in the form:

\[
\text{contr} (\nabla_{t_1 \ldots t_{A_1}} R_{t_1 j_1 k_1 l_1} \otimes \cdots \otimes R_{t_2 j_2 k_2 l_2} \otimes R_{t_{A_1+\gamma} j_{A_1+\gamma} k_{A_1+\gamma} l_{A_1+\gamma}}) \\
\otimes (\tilde{\xi}^2)^\gamma (\nabla)^{s_1} \phi \otimes \cdots \otimes (\nabla)^{\tilde{\xi}^{A_1}} \phi
\]

(102)

where each a factor \( \nabla \phi \) contracts against an index in the factor \( \nabla_{\tilde{\xi} A_1} R_{ijkl} \).

As in all the previous cases, we have that:

\[
\text{Shad}_{\tilde{\phi}} [I_{g^n}^{\tilde{\phi} - A_1} (\phi)] = 0
\]

(103)

modulo \( \tilde{\xi} \)-contractions of length \( \geq \frac{n}{2} + 1 \), since the shadow divergence formula holds formally.
As before, for each $C_u^n(\phi)$ that is subsequent to the critical list, we have that $\text{Tail}^+_{Shad}[C_u^n(\phi)] = 0$. Hence, we have that:

$$\Sigma_{g \in G_a} Shad_+ [C_g^n(\phi)] + \Sigma_{u \in U_{crit}} a_u Shad_+ [C_u^n(\phi)] = 0$$  \hspace{1cm} (104)

modulo $\vec{\xi}$-contractions of $\vec{\xi}$-length $\geq \frac{n}{2} + 1$.

Moreover, for each $u \in U_{crit}$, where $C_u^n(\phi)$ is in the form:

$$\text{contr}(R_{i_1j_1k_1l_1} \otimes \cdots \otimes R_{i_{A_1-\gamma}j_{A_1-\gamma}k_{A_1-\gamma}l_{A_1-\gamma}} \otimes R^\gamma \otimes \Delta \phi \otimes \cdots \otimes \Delta \phi)$$  \hspace{1cm} (105)

we have that $\text{Tail}^+_{Shad}[C_u^n(\phi)]$ can be written out as:

$$\text{Tail}^+_{Shad}[C_u^n(\phi)] = \Sigma_{h=1}^{A_1-\gamma} C_u^{n,h}(\phi)$$  \hspace{1cm} (106)

where $C_u^{n,h}(\phi)$ is in the form:

$$\text{contr}(R_{i_1j_1k_1l_1} \otimes \cdots \otimes \nabla_{i_1} \cdots \nabla_{i_{A_1-\gamma}} R_{i_kj_kk_h} \otimes \cdots \otimes R_{i_{A_1-\gamma}j_{A_1-\gamma}k_{A_1-\gamma}l_{A_1-\gamma}} \otimes ([\vec{\xi}]^2 \gamma \otimes \nabla_{i_1} \phi \otimes \cdots \otimes \nabla_{i_{A_1-\gamma}} \phi)$$  \hspace{1cm} (107)

We then define $C_u^n(g^n)$ to stand for the complete contraction:

$$\text{contr}(R_{i_1j_1k_1l_1} \otimes \cdots \otimes R_{i_{A_1-\gamma}j_{A_1-\gamma}k_{A_1-\gamma}l_{A_1-\gamma}})$$

Hence, using the equation (104) and repeating the same argument as in the above case, we may determine the sublinear combination $\Sigma_{u \in U_{crit}} a_u C_u^n(g^n)$, and hence also the sublinear combination $\Sigma_{u \in U_{crit}} a_u C_u^n(g^n)$ (104) (106) (107) (108) (109). We have completed the proof of Lemma 2.
