# Weak Turbulence for a 2D periodic Schrödinger Equation 

J. Colliander (University of Toronto) and G. Staffilani (MIT)

January 17, 2008

1 Introduction: Weak Turbulence for NLS

2 Resonant Truncation of $\operatorname{NLS}\left(\mathbb{T}^{2}\right)$

3 Abstract Combinatorial Resonant Set $\wedge$

## The NLS Initial Value Problem

We consider the defocusing initial value problem:

$$
\left\{\begin{array}{c}
\left(-i \partial_{t}+\Delta\right) u=|u|^{2} u  \tag{2}\\
u(0, x) \stackrel{=}{=} u_{0}(x), \text { where } x \in \mathbb{T}^{2}, \mathbb{R}^{2} .
\end{array}\right.
$$

Smooth solution $u(x, t)$ exists globally and

$$
\begin{aligned}
& \text { Mass }=M(u)=\|u(t)\|^{2}=M(0) \\
& \text { Energy }=E(u)=\int\left(\frac{1}{2}|\nabla u(t, x)|^{2}+\frac{1}{4}|u(x, t)|^{4}\right) d x=E(0)
\end{aligned}
$$

In particular if $f_{t}(\xi)=|\hat{u}(t, \xi)|^{2}$ then the area of the subgraph of $f_{t}(\xi)$ remains constant. On the other hand the shape of the subgraph may change in time, in particular in time most of the area may concentrate on very high frequencies.

## Notion of Weak Turbulence

## DEFINITION

Weak turbulence is the phenomenon of global-in-time solutions shifting their mass toward increasingly high frequencies.

This shift is also called forward cascade.

- One way of measuring weak turbulence is to consider the function

$$
\|u(t)\|_{\dot{H}^{s}}^{2}=\int|\hat{u}(t, \xi)|^{2}|\xi|^{2 s} d \xi
$$

and prove that it grows for large times $t$.

- Weak turbulence is incompatible with scattering and complete integrability.

## Incompatible with Scattering \& Integrability

- Scattering: In this context scattering (at $+\infty$ ) means that for any global solution $u(t, x) \in H^{s}$ there exists $u_{0}^{+} \in H^{s}$ such that, if $S(t)$ is the linear Schrödinger operator, then

$$
\lim _{t \rightarrow+\infty}\left\|u(t, x)-S(t) u_{0}^{+}(x)\right\|_{H^{s}}=0
$$

Since $\left\|S(t) u_{0}^{+}\right\|_{H^{s}}=\left\|u_{0}^{+}\right\|_{H^{s}}$, it follows that $\|u(t)\|_{\dot{H}^{s}}^{2}$ will not grow.
■ Complete Integrability: The 1d equation

$$
\left(i \partial_{t}+\Delta\right) u=-|u|^{2} u
$$

is integrable in the sense that it admits infinitely many conservation laws. Combining them in the right way one gets that $\|u(t)\|_{\dot{H}^{s}}^{2} \leq C_{s}$ for all times.

## Past Results

- Bourgain: (late 90's)

For the periodic IVP $\operatorname{NLS}\left(\mathbb{T}^{2}\right)$ one can prove

$$
\|u(t)\|_{\dot{H}^{s}}^{2} \leq C_{s}|t|^{4 s}
$$

The idea here is to improve the local estimate for $t \in[-1,1]$

$$
\|u(t)\|_{H^{s}} \leq C_{s}\|u(0)\|_{H^{s}}, \quad \text { for } C_{s} \gg 1
$$

to the better one

$$
\|u(t)\|_{H^{s}} \leq 1\|u(0)\|_{H^{s}}+C_{s}\|u(0)\|_{H^{s}}^{1-\delta} \quad \text { for } C_{s} \gg 1
$$

for some $\delta>0$. This last one in fact gives

$$
\|u(t)\|_{H^{s}} \leq C_{s}|t|^{1 / \delta}
$$

■ Improvements: Staffilani, Colliander-Delort-Kenig-Staffilani.

## Past Results

- Bourgain: (late 90's)

Given $m, s \gg 1$ there exists $\tilde{\Delta}$ such that a global solution $u(x, t)$ to the modified wave equation

$$
\left(\partial_{t t}-\tilde{\Delta}\right) u=u^{p}
$$

such that

$$
\|u(t)\|_{H^{s}} \sim|t|^{m}
$$

- Numerics?

## Conjecture

Solutions to dispersive equations on $\mathbb{R}^{d}$ DO NOT exhibit weak turbulence. Solutions to dispersive equations on $\mathbb{T}^{d}$ DO exhibit weak turbulence. In particular for $\operatorname{NLS}\left(\mathbb{T}^{2}\right)$

$$
\|u(t)\|_{\dot{H}^{s}}^{2} \rightarrow \infty \text { as } t \rightarrow \infty
$$

## Main Theorem

## Theorem (Colliander-Keel-Staffilani-Takaoka-Tao)

Let $s>1, k \gg 1$ and $0<\sigma<1$ be given. Then there exists a global smooth solution $u(x, t)$ to

$$
\left\{\begin{array}{c}
\left(-i \partial_{t}+\Delta\right) u=|u|^{2} u  \tag{2}\\
u(0, x)=u_{0}(x), \text { where } x \in \mathbb{T}^{2}
\end{array}\right.
$$

and $T>0$ such that

$$
\left\|u_{0}\right\|_{H^{s}} \leq \sigma
$$

and

$$
\|u(t)\|_{\dot{H}^{s}}^{2} \geq K
$$

## Ingredients for the proof

1 Reduction to a resonant problem RFNLS
2 Construction of a special finite set $\Lambda$ of frequencies
3 Truncation to a resonant, finite- $d$ Toy Model
4 Arnold diffusion for the Toy Model
5 Approximation result via perturbation lemma
6 A scaling argument

## 2. Resonant Truncation of $\operatorname{NLS}\left(\mathbb{T}^{2}\right)$

We consider the gauge transformation

$$
v(t, x)=e^{-i 2 G t} u(t, x)
$$

for $G \in \mathbb{R}$. If $u$ solves $\operatorname{NLS}\left(\mathbb{T}^{2}\right)$ above, then $v$ solves the equation

$$
\begin{equation*}
\left(-i \partial_{t}+\Delta\right) v=(2 G+v)|v|^{2} \tag{NLS}
\end{equation*}
$$

We make the ansatz

$$
v(t, x)=\sum_{n \in \mathbb{Z}^{2}} a_{n}(t) e^{i\left(\langle n, x\rangle+|n|^{2} t\right)}
$$

Now the dynamics is all recast trough $a_{n}(t)$ :

$$
-i \partial_{t} a_{n}=2 G a_{n}+\sum_{n_{1}-n_{2}+n_{3}=n} a_{n_{1}} a_{n_{2}}^{-} a_{n_{3}} e^{i \omega_{4} t}
$$

where $\omega_{4}=\left|n_{1}\right|^{2}-\left|n_{2}\right|^{2}+\left|n_{3}\right|^{2}-|n|^{2}$.

## The FNLS system

By choosing

$$
G=-\|v(t)\|_{L^{2}}^{2}=-\sum_{k}\left|a_{k}(t)\right|^{2}
$$

which is constant from the conservation of the mass, one can rewrite the equation above as

$$
-i \partial_{t} a_{n}=-a_{n}\left|a_{n}\right|^{2}+\sum_{n_{1}, n_{2}, n_{3} \in \Gamma(n)} a_{n_{1}} a_{n_{2}}^{-} a_{n_{3}} e^{i \omega_{4} t}
$$

where

$$
\Gamma(n)=\left\{n_{1}, n_{2}, n_{3} \in \mathbb{Z}^{2} / n_{1}-n_{2}+n_{3}=n ; n_{1} \neq n ; n_{3} \neq n\right\} .
$$

From now on we will be refering to this system as the FNLS system, with the obvious connection with the original $N L S\left(\mathbb{T}^{2}\right)$ equation.

## The RFNLS SYstem

We define the set

$$
\Gamma_{r e s}(n)=\left\{n_{1}, n_{2}, n_{3} \in \Gamma(n) / \omega_{4}=0\right\} .
$$

The geometric interpretation for this set is the following: If $n_{1}, n_{2}, n_{3}$ are in $\Gamma_{\text {res }}(n)$, then these four points represent the vertices of a rectangle in $\mathbb{Z}^{2}$.
We finally define the Resonant Truncation RFNLS to be the system

$$
-i \partial_{t} b_{n}=-b_{n}\left|b_{n}\right|^{2}+\sum_{n_{1}, n_{2}, n_{3} \in \Gamma_{r e s}(n)} b_{n_{1}} \overline{b_{n_{2}}} b_{n_{3}} e^{i \omega_{4} t}
$$

## Finite Dimensional Resonant TRUNCATION

- A set $\Lambda \subset \mathbb{Z}^{2}$ is closed under resonant interactions if

$$
n_{1}, n_{2}, n_{3} \in \Gamma_{r e s}(n), n_{1}, n_{2}, n_{3} \in \Lambda \Longrightarrow n \in \Lambda
$$

- A finite dimensional resonant truncation of $\mathcal{F} N L S$ is

$$
-i \partial_{t} b_{n}=-b_{n}\left|b_{n}\right|^{2}+\sum_{n_{1}, n_{2}, n_{3} \in \Gamma_{\text {res }}(n) \cap \Lambda^{3}} b_{n_{1}} \bar{b}_{n_{2}} b_{n_{3}} .\left(R \mathcal{F} N L S_{\Lambda}\right)
$$

- $\forall$ resonant-closed finite $\Lambda \subset \mathbb{Z}^{2} R \mathcal{F} N L S_{\Lambda}$ is an ODE.

We will construct a special set $\Lambda$ of frequencies.

## 3. Abstract Combinatorial Resonant Set $\Lambda$

Imagine a resonant-closed $\Lambda=\Lambda_{1} \cup \cdots \cup \Lambda_{M}$ with properties. Define a nuclear family to be a rectangle ( $n_{1}, n_{2}, n_{3}, n_{4}$ ) where the frequencies $n_{1}, n_{3}$ (the 'parents') live in generation $\Lambda_{j}$ and $n_{2}, n_{4}$ ('children') live in generation $\Lambda_{j+1}$.

■ Existence and uniqueness of spouse and children: $\forall 1 \leq j<M$ and $\forall n_{1} \in \Lambda_{j} \exists$ unique nuclear family such that $n_{1}, n_{3} \in \Lambda_{j}$ are parents and $n_{2}, n_{4} \in \Lambda_{j+1}$ are children.

- Existence and uniqueness of siblings and parents: $\forall 1 \leq j<M$ and $\forall n_{2} \in \Lambda_{j+1} \exists$ unique nuclear family such that $n_{2}, n_{4} \in \Lambda_{j+1}$ are children and $n_{1}, n_{3} \in \Lambda_{j}$ are parents.
- No incest: The sibling of a frequency is never its spouse.

■ Faithfulness: Besides nuclear families, $\Lambda$ contains no other rectangles.

- Integenerational Equality:The function $n \longmapsto a_{n}(0)$ is constant on each generation $\Lambda_{j}$.

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## Cartoon Construction of $\Lambda$

## More properties for the set $\Lambda$

- Multiplicative Structure: If $N=N(\sigma, K)$ is large enough then $\Lambda$ consists of $M \times 2^{M-1}$ disjoint frequencies $n$ with $|n|>N=N(\sigma, K)$ and the last frequency in $\Lambda_{M}$ is of size $C(M) N$ with the first in $\Lambda_{1}$ is of size $N$. We call $N$ the Inner Radius of $\Lambda$.
- Wide Diaspora: Given $\sigma \ll 1$ and $K \gg 1$, there exist $M$ and $\Lambda=\Lambda_{1} \cup \ldots \cup \Lambda_{M}$ as above and

$$
\sum_{n \in \Lambda_{M}}|n|^{2 s} \geq \frac{K^{2}}{\sigma^{2}} \sum_{n \in \Lambda_{1}}|n|^{2 s}
$$

- Approximation: If $\operatorname{spt}\left(a_{n}(0)\right) \subset \Lambda$ then $\mathcal{F} N L S$-evolution $a_{n}(0) \longmapsto a_{n}(t)$ is nicely approximated by $R \mathcal{F} N L S_{\Lambda}-\mathrm{ODE}$ $a_{n}(0) \longmapsto b_{n}(t)$.
- Given $\epsilon, s, K$, build $\Lambda$ so that $R \mathcal{F} N L S_{\Lambda}$ has weak turbulence.

## The system RFNLS $_{\wedge}$ and the Toy Model

- The truncation of RFNLS to the constructed set $\Lambda$ is the ODE

$$
-i \partial_{t} b_{n}=-b_{n}\left|b_{n}\right|^{2}+\sum_{n_{1}, n_{2}, n_{3} \in \Lambda \cap \Gamma_{r e s}(n)} b_{n_{1}} b_{n_{2}} b_{n_{3}} . \quad\left(R F N L S_{\Lambda}\right)
$$

■ Intergenerational equality hypothesis $\left(n \longmapsto b_{n}(0)\right.$ is constant on each generation $\Lambda_{j}$.) persists under $R F N L S_{\Lambda}$ :

$$
\forall m, n \in \Lambda_{j}, \quad b_{n}(t)=b_{m}(t)
$$

- $R F N L S_{\Lambda}$ may be reindexed by generation number $j$. The recast dynamics is the Toy Model (ODE):
$-i \partial_{t} b_{j}(t)=-b_{j}(t)\left|b_{j}(t)\right|^{2}-2 b_{j-1}(t)^{2} \overline{b_{j}(t)}-2 b_{j+1}(t)^{2} \overline{b_{j}(t)}$, with the boundary condition

$$
\begin{equation*}
b_{0}(t)=b_{M+1}(t)=0 \tag{BC}
\end{equation*}
$$

## Conservation laws for the ODE system

The following are conserved quantities for (ODE)

$$
\begin{aligned}
& \text { Mass }=\sum_{j}\left|b_{j}(t)\right|^{2}=C_{0} \\
& \text { Momentum }=\sum_{j}\left|b_{j}(t)\right|^{2} \sum_{n \in \Lambda_{j}} n=C_{1},
\end{aligned}
$$

and if

$$
\begin{aligned}
& \text { Kinetic Energy }=\sum_{j}\left|b_{j}(t)\right|^{2} \sum_{n \in \Lambda_{j}}|n|^{2} \\
& \text { Potential Energy }=\frac{1}{2} \sum_{j}\left|b_{j}(t)\right|^{4}+\sum_{j}\left|b_{j}(t)\right|^{2}\left|b_{j+1}(t)\right|^{2}
\end{aligned}
$$

then

$$
\text { Energy }=\text { Kinetic Energy }+ \text { Potential Energy }=C_{2} .
$$

4. Arnold Diffusion for the Toy Model ODE

## Toy model travelling wave solution

Using dynamical systems methods, we construct a Toy Model ODE evolution $b_{j}(0) \longmapsto b_{j}(t)$ such that:

$$
\begin{aligned}
\left(b_{1}(0), b_{2}(0), \ldots, b_{M}(0)\right) & \sim(1,0, \ldots, 0) \\
\left(b_{1}\left(t_{2}\right), b_{2}\left(t_{2}\right), \ldots, b_{M}\left(t_{2}\right)\right) & \sim(0,1, \ldots, 0)
\end{aligned}
$$

$$
\left(b_{1}\left(t_{M}\right), b_{2}\left(t_{M}\right), \ldots, b_{M}\left(t_{M}\right)\right) \sim(0,0, \ldots, 1)
$$

Bulk of conserved mass is transferred from $\Lambda_{1}$ to $\Lambda_{M}$. Weak turbulence lower bound follows from Wide Diaspora Property.

## Arnold Diffusion for ODE: The set up

Global well-posedness for $O D E$ is not an issue. We define

$$
\Sigma=\left\{x \in \mathbb{C}^{M} /|x|^{2}=1\right\} \text { and } W(t): \Sigma \rightarrow \Sigma
$$

where $W(t) b\left(t_{0}\right)=b\left(t+t_{0}\right)$ for any solution $b(t)$ of $O D E$. It is easy to see that for any $b \in \Sigma$

$$
\partial_{t}\left|b_{j}\right|^{2}=4 \Re\left(i \bar{b}_{j}^{2}\left(b_{j-1}^{2}+b_{j+1}^{2}\right)\right) \leq 4\left|b_{j}\right|^{2}
$$

So if

$$
b_{j}(0)=0 \Longrightarrow b_{j}(t)=0, \quad \text { for all } t \in[0, T] .
$$

If moreover we define the torus

$$
\Pi_{j}=\left\{\left(b_{1}, \ldots ., b_{M}\right) \in \Sigma /\left|b_{j}\right|=1, b_{k}=0, k \neq j\right\}
$$

then

$$
W(t) \Pi_{j}=\Pi_{j} \text { for all } j=1, \ldots ., M
$$

( $\Pi_{j}$ is invariant).

## Arnold Diffusion for ODE

## Theorem

(Arnold Diffusion)
Let $M \geq 6$. Given $\epsilon>0$ there exist $x_{3}$ within $\epsilon$ of $\Pi_{3}$ and $x_{M-2}$ within $\epsilon$ of $\Pi_{M-2}$ and a time $t$ such that

$$
W(t) x_{3}=x_{M-2} .
$$

## Remark

$W(t) x_{3}$ is a solution of total mass 1 arbitrarily concentrated at mode $j=3$ at some time $t_{0}$ and then arbitrarily concentrated at mode $j=M-2$ at later time $t$.

## Intuition

Consider $M=2$. Then $O D E$ is of the form

$$
\begin{aligned}
\partial_{t} b_{1} & =-i\left|b_{1}\right|^{2} b_{1}+2 i \overline{b_{1}} b_{2}^{2} \\
\partial_{t} b_{2} & =-i\left|b_{2}\right|^{2} b_{2}+2 i \overline{b_{2}} b_{1}^{2}
\end{aligned}
$$

This system has explicit solution

$$
b_{1}(t)=\frac{e^{-i t}}{\sqrt{1+e^{2 \sqrt{3} t}}} \omega b_{2}(t)=\frac{e^{-i t}}{\sqrt{1+e^{-2 \sqrt{3} t}}} \omega^{2}
$$

where $\omega=e^{2 i \pi / 3}$ (cube root of unity). Since

$$
\lim _{t \rightarrow+\infty}\left|b_{1}(t)\right|=0 \text { and } \lim _{t \rightarrow+\infty}\left|b_{2}(t)\right|=1
$$

and

$$
\lim _{t \rightarrow-\infty}\left|b_{2}(t)\right|=0 \text { and } \lim _{t \rightarrow-\infty}\left|b_{1}(t)\right|=1
$$

## More Intuition

It follows that $\left(b_{1}, b_{2}\right) \in \Pi_{2}$ at $t=+\infty$ and $\left(b_{1}, b_{2}\right) \in \Pi_{1}$ at $t=-\infty$. So with an infinite amount of time one can go from $\Pi_{1}$ to $\Pi_{2}$ and viceversa. A suitable perturbation of $\Pi_{i}$ replacing the tori $\Pi_{i}$ will be the key in proving diffusion in finite time:
A picture here?

## A perturbation lemma

## LEMMA

Let $\Lambda \subset \mathbb{Z}^{2}$ introduced above. Let $B \gg 1$ and $\delta>0$ small and fixed. Let $t \in[0, T]$ and $T \sim B^{2} \log B$. Suppose there exists $b(t) \in I^{1}(\Lambda)$ solving $R F N L S_{\Lambda}$ such that

$$
\|b(t)\|_{1^{1}} \lesssim B^{-1}
$$

Then there exists a solution $a(t) \in I^{1}\left(\mathbb{Z}^{2}\right)$ of RFNLS such that

$$
a(0)=b(0), \quad \text { and } \quad\|a(t)-b(t)\|_{1^{1}\left(\mathbb{Z}^{2}\right)} \lesssim B^{-1-\delta},
$$

for any $t \in[0, T]$.

## Proof.

This is a standard perturbation lemma proved by checking that the " non resonant" part of the nonlinearity remains small enough.

## RECASting THE MAIN THEOREM

With all the notations and reductions introduced we can now recast the main theorem in the following way:

## Theorem

For any $0<\sigma \ll 1$ and $K \gg 1$ there exists a complex sequence $\left(a_{n}\right)$ such that

$$
\left(\sum_{n \in \mathbb{Z}^{2}}\left|a_{n}\right|^{2}|n|^{2 s}\right)^{1 / 2} \lesssim \sigma
$$

and a solution $\left(a_{n}(t)\right)$ of (FNLS) and $T>0$ such that

$$
\left(\sum_{n \in \mathbb{Z}^{2}}\left|a_{n}(T)\right|^{2}|n|^{2 s}\right)^{1 / 2}>K
$$

## Scaling ARgument

In order to be able to use the Arnold Diffusion to move mass from lower frequencies to higher ones and start with a small data we ned to introduce scaling. Consider in $[0, t]$ the solution $b(t)$ of the system $R F N L S_{\Lambda}$ with initial datum $b_{0}$. Then the rescaled function

$$
b^{\lambda}(t)=\lambda^{-1} b\left(\frac{t}{\lambda^{2}}\right)
$$

solves the same system with datum $b_{0}^{\lambda}=\lambda^{-1} b_{0}$.
We then first pick the complex vector $b(0)$ that was found in the theorem on Arnold Diffusion. For simplicity let's assume here that $b_{j}(0)=1-\epsilon$ if $j=3$ and $b_{j}(0)=\epsilon$ if $j \neq 3$ and then we fix

$$
a_{n}(0)=\left\{\begin{aligned}
b_{j}^{\lambda}(0) & \text { for any } n \in \Lambda_{j} \\
0 & \text { otherwise } .
\end{aligned}\right.
$$

## Estimating the size of $(a(0))$

By definition

$$
\left(\sum_{n \in \Lambda}\left|a_{n}(0)\right|^{2}|n|^{2 s}\right)^{1 / 2}=\lambda^{-1}\left(\sum_{j=1}^{M}\left|b_{j}(0)\right|^{2}\left(\sum_{n \in \Lambda_{j}}|n|^{2 s}\right)\right)^{1 / 2}=\lambda^{-1} Q_{3}
$$

where the last equality follows from defining

$$
\sum_{n \in \Lambda_{j}}|n|^{2 s}=Q_{j}
$$

and the definition of $a_{n}(0)$ given above. At this point we use the proprieties of the set $\Lambda$ to estimate $Q_{3}=C(M) N$, where $N$ is the inner radius of $\Lambda$. We then conclude that

$$
\left(\sum_{n \in \Lambda}\left|a_{n}(0)\right|^{2}|n|^{2 s}\right)^{1 / 2}=\lambda^{-1} C(M) N^{s} \sim \sigma
$$

## Estimating the size of $(a(T))$

By using the perturbation lemma with $B=\lambda$ and $T=\lambda^{2} t$ we have

$$
\|a(T)\|_{H^{s}} \geq\left\|b^{\lambda}(T)\right\|_{H^{s}}-\left\|a(T)-b^{\lambda}(T)\right\|_{H^{s}}=I_{1}-I_{2}
$$

We want $I_{2} \ll 1$ and $I_{1}>K$. For the first
$I_{2} \leq\left\|a(T)-b^{\lambda}(T)\right\|_{I^{1}\left(\mathbb{Z}^{2}\right)}\left(\sum_{n \in \Lambda}|n|^{2 s}\right)^{1 / 2} \lesssim \lambda^{-1-\delta}\left(\sum_{n \in \Lambda}|n|^{2 s}\right)^{1 / 2}$.
As above

$$
I_{2} \lesssim \lambda^{-1-\delta} C(M) N^{s}
$$

At this point we need to pick $\lambda$ and $N$ so that

$$
\|a(0)\|_{H^{s}}=\lambda^{-1} C(M) N^{s} \sim \sigma \text { and } I_{2} \lesssim \lambda^{-1-\delta} C(M) N^{s} \ll 1
$$

and thanks to the presence of $\delta>0$ this can be achieved by taking $\lambda$ and $N$ large enough.

## Estimating $I_{1}$

It is important here that at time zero one starts with a fixed non zero datum, namely $\|a(0)\|_{H^{s}}=\left\|b^{\lambda}(0)\right\|_{H^{s}} \sim \sigma>0$. In fact we will show that

$$
I_{1}^{2}=\left\|b^{\lambda}(T)\right\|_{H^{s}}^{2} \geq \frac{K^{2}}{\sigma^{2}}\left\|b^{\lambda}(0)\right\|_{H^{s}}^{2} \sim K^{2}
$$

If we define for $T=\lambda^{2} t$

$$
R=\frac{\sum_{n \in \Lambda}\left|b_{n}^{\lambda}\left(\lambda^{2} t\right)\right|^{2}|n|^{2 s}}{\sum_{n \in \Lambda}\left|b_{n}^{\lambda}(0)\right|^{2}|n|^{2 s}}
$$

then we are reduce to showing that $R \gtrsim K^{2} / \sigma^{2}$. Now recall the notation

$$
\Lambda=\Lambda_{1} \cup \ldots . . \cup \Lambda_{M} \quad \text { and } \quad \sum_{n \in \Lambda_{j}}|n|^{2 s}=Q_{j}
$$

## More on Estimating $I_{1}$

Using the fact that by the theorem on Arnold Diffusion (approximately) one obtains $b_{j}(T)=1-\epsilon$ if $j=M-2$ and $b_{j}(T)=\epsilon$ if $j \neq M-2$, it follows that

$$
\begin{aligned}
R & =\frac{\sum_{i=1}^{M} \sum_{n \in \Lambda_{i}}\left|b_{i}^{\lambda}\left(\lambda^{2} t\right)\right|^{2}|n|^{2 s}}{\sum_{i=1}^{M} \sum_{n \in \Lambda_{i}}\left|b_{i}^{\lambda}(0)\right|^{2}|n|^{2 s}} \\
& \geq \frac{Q_{M-2}(1-\epsilon)}{(1-\epsilon) Q_{3}+\epsilon Q_{1}+\ldots .+\epsilon Q_{M}} \sim \frac{Q_{M-2}(1-\epsilon)}{Q_{M-2}\left[(1-\epsilon) \frac{Q_{3}}{Q_{M-2}}+\ldots .+\epsilon\right]} \\
& \gtrsim \frac{(1-\epsilon)}{(1-\epsilon) \frac{Q_{3}}{Q_{M-2}}}=\frac{Q_{M-2}}{Q_{3}}
\end{aligned}
$$

and the conclusion follows from one the properties of the sets $\Lambda_{j}$ :

$$
Q_{M-2}=\sum_{n \in \Lambda_{M-2}}|n|^{2 s} \gtrsim \frac{K^{2}}{\sigma^{2}} \sum_{n \in \Lambda_{3}}|n|^{2 s}=\frac{K^{2}}{\sigma^{2}} Q_{3}
$$

## Conclusions

Can one obtain a stronger result? We believe that by "concatenating" infinitely many solutions like the one described above one may be able to obtain a solution $u$ for $N L S\left(\mathbb{T}^{2}\right)$ such that

$$
\|u(t)\|_{H}^{s} \sim C_{s} \log (|t|), \quad \text { as } \quad t \rightarrow \pm \infty
$$
