

The helicity uniqueness conjecture in 3D hydrodynamics

Boris Khesin*, Daniel Peralta-Salas† and Cheng Yang‡

Abstract

We prove that the helicity is the only regular Casimir function for the coadjoint action of the volume-preserving diffeomorphism group $\text{SDiff}(M)$ on smooth exact divergence-free vector fields on a closed three-dimensional manifold M . More precisely, any regular C^1 functional defined on the space of C^∞ (more generally, C^k , $k \geq 4$) exact divergence-free vector fields and invariant under arbitrary volume-preserving diffeomorphisms can be expressed as a C^1 function of the helicity. This gives a complete description of Casimirs for adjoint and coadjoint actions of $\text{SDiff}(M)$ in 3D and completes the proof of Arnold-Khesin's 1998 conjecture for a manifold M with trivial first homology group. Our proofs make use of different tools from the theory of dynamical systems, including normal forms for divergence-free vector fields, the Poincaré-Birkhoff theorem, and a division lemma for vector fields with hyperbolic zeros.

1 Introduction

Let (M, g) be a closed (i.e., compact and without boundary) three-dimensional Riemannian manifold with volume form $d\mu$. The motion of an inviscid and incompressible fluid filling M is governed by the *Euler equations*:

$$\begin{cases} \partial_t v + \nabla_v v = -\nabla p, \\ \operatorname{div} v = 0, \end{cases} \quad (1)$$

where $\nabla_v v$ is the Riemannian covariant derivative of the field v along itself, div is the divergence operator, and the pressure function p is uniquely determined up to an additive constant.

In the 1960's, Moreau [12] and Moffatt [13] discovered a conserved quantity for the Euler equations, the *helicity*, which is a functional defined for the vorticity vector field $\omega := \operatorname{curl} v$ as follows:

$$\mathcal{H}(\omega) := \int_M \omega \cdot \operatorname{curl}^{-1} \omega \, d\mu = \int_M \omega \cdot v \, d\mu.$$

Here the dot \cdot denotes the (pointwise) Riemannian inner product of two fields. The operator curl is defined via differential forms as $i_{\operatorname{curl} v} d\mu = dv^\flat$, where v^\flat is the metric-dual 1-form of v . The origin of the helicity conservation is Kelvin's law of the vorticity transport by the flow. Actually, it is easy to check that $\mathcal{H}(\Phi_* \omega) = \mathcal{H}(\omega)$ for any (orientation-preserving)

volume-preserving diffeomorphism $\Phi : M \rightarrow M$, i.e., the helicity is invariant under arbitrary volume-preserving transformations, rather than under the specific family of diffeomorphisms defined by a fluid flow. In geometric terms, this makes the helicity a Casimir functional for the coadjoint action of the group of C^∞ volume-preserving diffeomorphisms on exact divergence-free vector fields. Note that the helicity \mathcal{H} is defined only on exact divergence-free vector fields, since it requires finding the field-potential, curl^{-1} .

In the 1998 monograph [4, Section I.9] it was conjectured that the helicity is the only Casimir function for the group $\text{SDiff}(M)$ of C^∞ volume-preserving diffeomorphisms of a closed 3D manifold M . In this paper we prove this conjecture for manifolds M with the trivial first homology group (where all divergence-free vector fields are exact), and under some natural regularity assumptions on the invariants. Furthermore, we establish similar results for the adjoint action of the group $\text{SDiff}(M)$ and for C^k -fields with $k \geq 4$. The case of M with $H_1(M, \mathbb{R}) \neq 0$ involves such an invariant of the adjoint action as the rotation number of a vector field, see [3], and we shall describe its interrelation with helicity.

To formulate the main result one needs the notion of regular integral invariants (see Definition 2.2), which, roughly speaking, means C^1 functionals on the space \mathfrak{X}_{ex}^k of exact C^k vector fields that are invariant under volume-preserving diffeomorphisms and whose (Fréchet) derivative is an integral operator with continuous kernel, see [6].

Theorem 1.1. *Let \mathcal{F} be a regular integral invariant on the space \mathfrak{X}_{ex}^k (endowed with the Whitney C^k topology). Then \mathcal{F} is a function of the helicity provided that $k \geq 4$ (including the case $k = \infty$), i.e. there exists a C^1 function $f : \mathbb{R} \rightarrow \mathbb{R}$ such that $\mathcal{F}(w) = f(\mathcal{H}(w))$ for any $w \in \mathfrak{X}_{ex}^k$.*

Corollary 1.2. *The helicity \mathcal{H} is the only regular Casimir (i.e. coadjoint invariant) for the group $\text{SDiff}(M)$ of C^∞ volume-preserving diffeomorphisms of a closed 3D manifold M (i.e. the conjecture of [4] holds) provided that $H_1(M, \mathbb{R}) = 0$.*

Concerning Corollary 1.2, we recall that when $H_1(M) = 0$, the dual space to the Lie algebra of the group $\text{SDiff}(M)$ can be identified with the space of C^∞ exact divergence-free vector fields endowed with the Whitney C^∞ topology (see Section 4 for details).

An analogous result for $k = 1$, i.e., for functionals acting on \mathfrak{X}_{ex}^1 , was proved in [6] (see also [10, 11] for the case of manifolds with boundary and divergence-free vector fields admitting a global cross section). However, none of the results for C^k implies the results for other k . The use of the space \mathfrak{X}_{ex}^1 (endowed with the Whitney C^1 topology) is key in the proof of [6], which is based on the existence of a residual subset of vector fields with special dynamical properties. Indeed, the strategy for C^1 -fields makes use of a theorem by M. Bessa [5] showing that there exists a dense set of vector fields in \mathfrak{X}_{ex}^1 that are topologically transitive; such a dense set of fields with a dense orbit cannot exist when one considers exact divergence-free vector fields of class C^4 or higher, as a consequence of the KAM theorem.

For the proof of Theorem 1.1 for C^k with $k \geq 4$ we use different (and somewhat more elementary) tools from the theory of dynamical systems, including normal forms for divergence-free vector fields, the Poincaré-Birkhoff theorem, and a division lemma for vector fields with hyperbolic zeros. The assumption $k \geq 4$ is due to the use of Sard's theorem, which requires sufficiently high regularity of the functions under consideration. In particular, it cannot be applied in the C^1 setting, where the corresponding functions are only C^0 . (Also note that although any C^1 -functional acting on \mathfrak{X}_{ex}^1 can also be evaluated at elements of \mathfrak{X}_{ex}^k , $k \geq 2$, the kernel of the derivative of such a functional on \mathfrak{X}_{ex}^k maps C^k vector fields into \mathfrak{X}_{ex}^1 only, and not into \mathfrak{X}_{ex}^k , so the second assumption in Definition 2.2 below would not be fulfilled.) The cases with $k = 2$ or 3 remain open.

Given a divergence-free vector field v on M one can define its rotation class $\lambda(v) \in H_1(M, \mathbb{R})$, see [3] and Section 4. Namely, for a three-dimensional manifold one can consider the cohomology class of the closed 2-form $i_v d\mu$ in $H^2(M, \mathbb{R})$, which is Poincaré isomorphic to $H_1(M, \mathbb{R})$.

Corollary 1.3. *The helicity \mathcal{H} is the only regular invariant of the adjoint action for the group $SDiff(M)$ on the space \mathfrak{X}_{ex}^k ($k \geq 4$) of exact divergence-free vector fields. For a manifold with nontrivial homology $H_1(M) \neq 0$ the rotation class $\lambda(v) \in H_1(M)$ of a vector field v is a regular invariant of the adjoint action of the identity connected component of the group $SDiff(M)$.*

The rotation class λ defines a natural projection $\lambda : \mathfrak{X}^k \rightarrow H_1(M)$, where $\mathfrak{X}_{ex}^k = \lambda^{-1}(0)$. So intuitively, the helicity (well-defined on \mathfrak{X}_{ex}^k) and the rotation class together constitute the set of regular invariants of the adjoint action. However for fields with nontrivial rotation class only relative helicity (of one field with respect to another) is well defined, see [4] for details.

This paper is organized as follows. In Section 2 we introduce the definition of regular integral invariants and prove the main theorem modulo Proposition 2.5. This proposition is proved in Section 3, thus completing the proof of the main result. In Section 4 we prove the corollaries and discuss in more detail the rotation class and the setting of adjoint and coadjoint actions on exact and non-exact divergence-free vector fields. Finally, in Section 5 we recall the geometric formulations of ideal hydrodynamics and magnetohydrodynamics, and explain how the previous results extend to the latter setting.

2 Regular integral invariants and proof of the main theorem

Consider the space \mathfrak{X}_{ex}^k , $k \in \{1, 2, \dots, \infty\}$ of *exact divergence-free vector fields* on a three-dimensional Riemannian manifold M . (The notation $\mathfrak{X}_{ex} \equiv \mathfrak{X}_{ex}^\infty$ stands for $k = \infty$.) Recall that a divergence-free field w is exact if it is the curl of another vector field, or, equivalently, if $i_w d\mu$ is an exact 2-form on M . The reason to consider the space \mathfrak{X}_{ex}^k is that the curl operator on exact fields has a well-defined inverse $\text{curl}^{-1} : \mathfrak{X}_{ex}^k \rightarrow \mathfrak{X}_{ex}^k$. In this context, one can define the helicity of an exact field as follows:

Definition 2.1. The *helicity* is the following quadratic form on $w \in \mathfrak{X}_{ex}^k$:

$$\mathcal{H}(w) := \int_M w \cdot \text{curl}^{-1} w \, d\mu.$$

It is well known [4] that the helicity is invariant under the action of the group $SDiff(M)$ of (smooth, orientation-preserving) volume-preserving diffeomorphisms of the manifold M , i.e. the helicity is a Casimir function of the group $SDiff(M)$. For now we need its infinitesimal invariance with respect to the action by a Lie derivative (or a Lie bracket) $L_v : \mathfrak{X}_{ex} \rightarrow \mathfrak{X}_{ex}$, where $w \mapsto [w, v]$ for any divergence-free vector field v . The fact that \mathfrak{X}_{ex} is dense in \mathfrak{X}_{ex}^k allows us to consider the L_v action by smooth fields v on \mathfrak{X}_{ex}^k ; we shall use this property in what follows without further mention.

Definition 2.2 [6]. Let $\mathcal{F} : \mathfrak{X}_{ex}^k \rightarrow \mathbb{R}$ be a C^1 functional. We say that \mathcal{F} is a *regular integral invariant* if:

1. It is invariant under the action of the volume-preserving diffeomorphism group $\text{SDiff}(M)$, i.e., $\mathcal{F}(w) = \mathcal{F}(\Phi_* w)$ for any $\Phi \in \text{SDiff}(M)$.
2. At any point $w \in \mathfrak{X}_{ex}^k$, the (Fréchet) derivative of \mathcal{F} is an integral operator with continuous kernel, that is,

$$(D\mathcal{F})_w(u) = \int_M K(w) \cdot u \, d\mu, \quad (2)$$

for any $u \in \mathfrak{X}_{ex}^k$, where $K : \mathfrak{X}_{ex}^k \rightarrow \mathfrak{X}_{ex}^k$ is a continuous map (with respect to the Whitney C^k topology). Here the dot stands for the Riemannian inner product of two vector fields on M .

Remark 2.3. The regular integral invariant $\mathcal{F} : \mathfrak{X}_{ex}^k \rightarrow \mathbb{R}$ is C^1 (or continuously differentiable) in the Fréchet sense, i.e., the Fréchet derivative $D\mathcal{F}$ is a continuous map. Depending on how we identify the dual space \mathfrak{X}_{ex}^* with \mathfrak{X}_{ex} , we obtain different regularities for the derivative $D\mathcal{F}$. Indeed, with the identification used in the context of the coadjoint action, introduced in Section 4.2, cf. Equation (7), we have that $(D\mathcal{F})_w = \text{curl } K(w)$, so $D\mathcal{F} : \mathfrak{X}_{ex}^k \rightarrow \mathfrak{X}_{ex}^{k-1}$. On the other hand, taking the pair between two exact fields to be the standard L^2 product, we have that $(D\mathcal{F})_w = K(w)$, and hence $D\mathcal{F} : \mathfrak{X}_{ex}^k \rightarrow \mathfrak{X}_{ex}^k$. However, this distinction will not be important in what follows because we shall not work with $D\mathcal{F}$, but directly with the kernel K .

It is easy to check that the helicity \mathcal{H} is a regular integral invariant (for any $k \geq 1$) with kernel

$$K(w) = 2 \text{curl}^{-1} w. \quad (3)$$

Note that in the case that the manifold M has trivial homology $H_1(M) = 0$, any divergence-free vector field is exact. Accordingly, in this case regular integral invariants on the space of smooth fields \mathfrak{X}_{ex} and regular Casimir functions of the Lie group $\text{SDiff}(M)$ are the same (cf. Section 4 for a proof).

Proof of the main theorem. The proof of Theorem 1.1 follows the strategy of [6], while the implementation turns out to be quite different in view of the different regularity of the vector fields.

Proposition 2.4. *For a regular invariant \mathcal{F} with kernel K on the space \mathfrak{X}_{ex}^k , $k \geq 1$ the kernel satisfies the following property: for any $w \in \mathfrak{X}_{ex}^k$ there exists a C^k function $J_w : M \rightarrow \mathbb{R}$ (depending on w) such that*

$$\text{curl } K(w) \times w = \nabla J_w. \quad (4)$$

Proof. By differentiating $\mathcal{F}((\phi_t)_*(w)) = \mathcal{F}(w)$ at $t = 0$ for a family of diffeomorphisms ϕ_t we obtain after certain transformations

$$0 = \frac{d}{dt} \mathcal{F}((\phi_t)_*(w))|_{t=0} = \int_M K(w) \cdot [w, v] \, d\mu = - \int_M v \cdot (\text{curl } K(w) \times w) \, d\mu$$

for any divergence-free velocity field $v := d\phi_t/dt(0) \in \mathfrak{X}(M)$. (One uses the relation $[w, v] = \text{curl}(v \times w)$ for divergence-free vector fields.) Due to arbitrariness of v this implies that the vector field $\text{curl } K(w) \times w$ is L^2 -orthogonal to all divergence-free vector fields on M , and hence it is a gradient field. \square

It turns out that for sufficiently smooth w one can prove a stronger result:

Proposition 2.5. *For the kernel K of a regular invariant \mathcal{F} on the space \mathfrak{X}_{ex}^k , $k \geq 4$, for any $w \in \mathfrak{X}_{ex}^k$ one has*

$$\operatorname{curl} K(w) \times w = 0.$$

We shall prove this key proposition in the next section. For now we assume it is true and continue with the proof of Theorem 1.1.

The equation $\operatorname{curl} K(w) \times w = 0$ implies that there exists a function $g \in C^{k-1}(M \setminus w^{-1}(0))$ defined in the complement of the zero set of w , such that

$$\operatorname{curl} K(w) = g w, \quad \text{with } g := \frac{w \cdot \operatorname{curl} K(w)}{|w|^2}.$$

Consider the set \mathcal{R} of exact divergence-free vector fields $w \in \mathfrak{X}_{ex}^k$, whose zeros are hyperbolic (and hence isolated, so there are finitely many of them). We will call vector fields in \mathcal{R} hyperbolic. A standard transversality argument (see e.g. [15, Chapter 2.3]) implies that \mathcal{R} is an open and dense set of \mathfrak{X}_{ex}^k . Take a vector field $w_0 \in \mathcal{R} \subset \mathfrak{X}_{ex}^k$.

Proposition 2.6. *The function $g_0(x)$ corresponding to a hyperbolic vector field $w_0 \in \mathcal{R} \subset \mathfrak{X}_{ex}^k$ can be extended to the whole manifold M as a C^{k-2} function, i.e. for any $w_0 \in \mathcal{R}$ there exists a function $g_0 \in C^{k-1}(M \setminus w_0^{-1}(0)) \cap C^{k-2}(M)$ such that $\operatorname{curl} K(w_0) = g_0(x) w_0$.*

Indeed, the equation $\operatorname{curl} K(w_0) \times w_0 = 0$ can be equivalently written as $i_{\operatorname{curl} K(w_0)} i_{w_0} d\mu = 0$. This implies collinearity of the vector fields $\operatorname{curl} K(w_0)$ and w_0 , and hence the existence of the required C^{k-1} function g_0 away from the zero set of w_0 . Furthermore, the set $w_0^{-1}(0)$ consists of finitely many points, which are hyperbolic zeros of the field w_0 . Then Proposition 2.6 immediately follows from the following version of Hadamard's division lemma, applied in a neighborhood of each zero of w_0 , which allows one to extend the function g_0 to a C^{k-2} -function on the entire M . The statement of this division lemma is local and can be formulated in local coordinates (x_i) in a neighborhood of the origin of \mathbb{R}^n .

Lemma 2.7. *Let $v = \sum \alpha_i \partial_{x_i}$ and $w = \sum \beta_i \partial_{x_i}$ be two C^l vector fields defined in a neighborhood V of $0 \in \mathbb{R}^n$, and $d\mu$ a volume form on \mathbb{R}^n . Assume that 0 is a hyperbolic zero of w . Then, if $i_v i_w d\mu = 0$ in V , there exists a function $h \in C^{l-1}(V)$, such that $\alpha_i = h(x) \beta_i$, for all $i = 1, \dots, n$.*

Proof. This is a finite-smoothness version of the theorem in [14] on zeros of differential forms, which is also a version of Hadamard's lemma. Due to the assumption $i_v i_w d\mu = 0$, these two fields are collinear outside of the origin and there exists a function $h \in C^l(V \setminus \{0\})$, such that $\alpha_i = h(x) \beta_i$, for all $i = 1, \dots, n$ and $x \neq 0$.

Since the field w has a hyperbolic singularity at 0 , one can use the functions β_i as local coordinates \tilde{x}_i near the origin; any function in the new coordinate system will be denoted with a "tilde". Since the collinearity assumption implies that v vanishes at the origin (otherwise the zero of w cannot be hyperbolic, this follows from a simple flow box argument), then $\tilde{\alpha}_i = 0$ for $\tilde{x}_i = 0$. One so has $\tilde{\alpha}_i = \tilde{h}_i(\tilde{x}) \tilde{x}_i$ by the classical Hadamard lemma, while the collinearity condition implies that $\tilde{h}_i = \tilde{h}_j = \tilde{h}$ in $V \setminus \{0\}$. The smoothness of h in the whole of V is less by 1 than that of $\tilde{\alpha}_i$, which is shown by a standard argument: in a convex neighborhood $\tilde{V} \subset V$ of the origin (in new coordinates) we can express the components $\tilde{\alpha}_i = \tilde{h}(\tilde{x}) \tilde{x}_i$ of the vector field v as follows:

$$\tilde{\alpha}_i(\tilde{x}) = \int_0^1 \frac{d}{dt} \tilde{\alpha}_i(\tilde{x}_1, \dots, t \tilde{x}_i, \dots, \tilde{x}_n) dt = \left(\int_0^1 \partial_i \tilde{\alpha}_i(\tilde{x}_1, \dots, t \tilde{x}_i, \dots, \tilde{x}_n) dt \right) \tilde{x}_i = \tilde{h}(\tilde{x}) \tilde{x}_i,$$

where $\tilde{h}(\tilde{x}) := \int_0^1 \partial_i \tilde{\alpha}_i(\tilde{x}_1, \dots, t\tilde{x}_i, \dots, \tilde{x}_n) dt$. Since $\tilde{\alpha}_i \in C^l(\tilde{V})$, one obtains that $\tilde{h} \in C^{l-1}(\tilde{V})$ and therefore $h = \tilde{h} \circ \beta \in C^{l-1}(V)$, where $\beta = (\beta_1, \beta_2, \dots, \beta_n)$. \square

Now, according to Proposition 2.6, we have the collinearity of the fields $\text{curl} K(w_0)$ and w_0 . This can be used to show that the derivatives of the functional \mathcal{F} and the helicity are proportional:

Proposition 2.8. *For a regular invariant functional \mathcal{F} on \mathfrak{X}_{ex}^k , there exists a continuous functional $\mathcal{C} : \mathfrak{X}_{ex}^k \setminus \{0\} \rightarrow \mathbb{R}$ such that*

$$(D\mathcal{F})_w = \mathcal{C}(w) (D\mathcal{H})_w,$$

for all $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$.

Proof. Since $0 = \text{div} \text{curl} K(w_0) = \nabla g_0 \cdot w_0$, we have that the function g_0 is a C^{k-2} first integral of the vector field $w_0 \in \mathcal{R}$ (more precisely, $g_0 \in C^{k-1}(M \setminus w_0^{-1}(0)) \cap C^{k-2}(M)$). The zero set of w_0 consists of finitely many points that we denote by $\{p_1, p_2, \dots, p_N\} \subset M$. Take the values $g_0(p_i) = c_i$, and a point $p \in M$ with $g_0(p) \neq c_i$ for all i . Since g_0 is C^{k-1} in the complement of the finite set $\{p_1, p_2, \dots, p_N\}$, Sard's theorem implies that one can safely assume that $g_0(p)$ is a regular value. It then follows from Lemma 3.1 (see Section 3), Thom's isotopy theorem and the compactness of the manifold that there is a domain U containing p which is trivially fibred by components of the level sets of g_0 , that are invariant tori of w_0 .

Now using Lemma 3.2 in Section 3, and arguing exactly as in the proof of Proposition 2.5, we conclude that g_0 must be a constant for any $w_0 \in \mathcal{R}$, i.e., one has that $\text{curl} K(w_0) = 2\mathcal{C}(w_0)w_0$ for all $w_0 \in \mathcal{R}$, where $\mathcal{C}(w_0)$ is a constant on M that only depends on the field w_0 . The continuity of the kernel K (which implies the continuity of the function g on \mathfrak{X}_{ex}^k), and the fact that g is a constant on M (that depends on w) for a dense subset \mathcal{R} of \mathfrak{X}_{ex}^k , imply that g must also be a constant (depending on w) for all $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$.

Summarizing, we have proved that there exists a continuous functional $\mathcal{C} : \mathfrak{X}_{ex}^k \setminus \{0\} \rightarrow \mathbb{R}$ such that the derivative of \mathcal{F} reads as

$$(D\mathcal{F})_w(u) = \int_M K(w) \cdot u \, d\mu = \int_M 2\mathcal{C}(w) \text{curl}^{-1}w \cdot u \, d\mu$$

for any $u \in \mathfrak{X}_{ex}^k$ and $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$. Noticing that the derivative of the helicity is given by $(D\mathcal{H})_w(u) = 2 \int_M \text{curl}^{-1}w \cdot u \, d\mu$, we obtain that

$$(D\mathcal{F})_w = \mathcal{C}(w) (D\mathcal{H})_w,$$

for all $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$. \square

Now, since the differentials of the functional \mathcal{F} and the helicity \mathcal{H} are proportional by Proposition 2.8 at each point of the space $\mathfrak{X}_{ex}^k \setminus \{0\}$, the main theorem will follow from the path-connectedness of the level sets of \mathcal{H} , which is established in the following proposition. This result was first proved in [6]. For the sake of completeness, here we give a simpler and more transparent proof.

Proposition 2.9 [6]. *The level sets of the helicity $\mathcal{H}^{-1}(c)$ are path-connected subsets of $\mathfrak{X}_{ex}^k \setminus \{0\}$.*

Proof. Let w_1 and w_2 be two exact divergence-free vector fields with the same helicity, which we first assume to be nonzero, i.e.

$$\mathcal{H}(w_1) = \mathcal{H}(w_2) = c \neq 0.$$

In order to prove the connectedness of the c -level, we introduce an auxiliary vector field $\bar{\beta} \in \mathfrak{X}_{ex}^k$ with the same helicity c , which can be connected with each w_0 and w_1 . The only ingredient we need in the proof is the property that the curl operator acting on the space \mathfrak{X}_{ex}^k of exact fields has infinitely many positive and negative eigenvalues, which implies that the positive and negative subspaces of the helicity quadratic form $\mathcal{H}(w)$ on \mathfrak{X}_{ex}^k are infinite-dimensional.

Assume that $c > 0$. Consider the subspace $\mathcal{S} \subset \mathfrak{X}_{ex}^k$ of vector fields orthogonal to the two vector fields w_1, w_2 with respect to the helicity quadratic form \mathcal{H} , that is

$$\mathcal{S} := \{u \in \mathfrak{X}_{ex}^k(M) : \int_M u \cdot \text{curl}^{-1} w_1 d\mu = \int_M u \cdot \text{curl}^{-1} w_2 d\mu = 0\}.$$

This space has codimension ≤ 2 and hence the restriction of the helicity \mathcal{H} to this subspace is still sign-indefinite. Hence, one can choose a vector field $\beta \in \mathcal{S}$ such that $\mathcal{H}(\beta) = 1$ (for $c < 0$ one needs to choose $\mathcal{H}(\beta) = -1$).

Now define a family of vector fields $w_t := tw_1 + f(t)\beta$ for $t \in [0, 1]$, and choose an appropriate function $f(t)$ so that the condition $\mathcal{H}(w_t) = c$ holds for all t . Namely,

$$\mathcal{H}(w_t) = \mathcal{H}(tw_1 + f(t)\beta) = t^2\mathcal{H}(w_1) + f(t)^2\mathcal{H}(\beta) = t^2c + f(t)^2,$$

where we have used that $\mathcal{H}(w_1) = c$, $\int_M \beta \cdot \text{curl}^{-1} w_1 d\mu = \int_M w_1 \cdot \text{curl}^{-1} \beta d\mu = 0$ and $\mathcal{H}(\beta) = 1$. Then, taking $f(t) := \sqrt{(1-t^2)c}$ for $t \in [0, 1]$ we obtain a continuous family w_t of fields in \mathfrak{X}_{ex}^k that have constant helicity c and connect $\bar{\beta} := \sqrt{c}\beta$ and w_1 . In the same way one can connect the fields w_2 and $\bar{\beta}$ for $t \in [-1, 0]$. The connecting path can be smoothed out by adjusting this construction. This proves the path-connectedness of the levels sets of the helicity for $c > 0$; a similar construction works for $c < 0$.

The case of $c = 0$ is analogous; take a (non-zero) field β with $\mathcal{H}(\beta) = 0$ and the family $w_t = tw_1 + (1-t)\beta$. Then $\mathcal{H}(w_t) = 0$ and this family provides the connectedness of the zero level set of the helicity, as required. \square

We are now ready to finish the proof of Theorem 1.1.

Proof. First, we recall that we showed in Proposition 2.8 that the derivative of the functional \mathcal{F} satisfies

$$(D\mathcal{F})_w = \mathcal{C}(w)(D\mathcal{H})_w \tag{5}$$

for all $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$ and some continuous functional $\mathcal{C}(w)$. Let us take any two exact vector fields on the level set $\{\mathcal{H} = c\}$ of the helicity, and connect them by a continuous path $w_t \in \mathfrak{X}_{ex}^k \setminus \{0\}$ (cf. Proposition 2.9) with constant helicity, i.e. $\mathcal{H}(w_t) = c$. The derivative of \mathcal{F} along this path is given by

$$(D\mathcal{F})_{w_t}(\dot{w}_t) = \mathcal{C}(w_t)(D\mathcal{H})_{w_t}(\dot{w}_t) = 0,$$

where \dot{w}_t is the tangent vector along the path for almost all t (actually, one can safely assume that the path is smooth in t). This implies that \mathcal{F} is also constant on each level set of \mathcal{H} . Accordingly, there exists a function $f : \mathbb{R} \rightarrow \mathbb{R}$ which assigns a value of \mathcal{F} to each value of

the helicity, i.e., $\mathcal{F}(w) = f(\mathcal{H}(w))$ for all $w \in \mathfrak{X}_{ex}^k \setminus \{0\}$. To include the case $w = 0$, we observe that \mathcal{F} is constant on the level set $\mathcal{H}^{-1}(0) \setminus \{0\}$, so the continuity of the functional \mathcal{F} in \mathfrak{X}_{ex}^k implies that it takes the same constant value on the whole level set $\mathcal{H}^{-1}(0)$, and hence the property $\mathcal{F}(w) = f(\mathcal{H}(w))$ holds for all $w \in \mathfrak{X}_{ex}^k$. Additionally, f is of class C^1 since \mathcal{F} itself is a C^1 functional. This completes the proof of Theorem 1.1. \square

3 Properties of the invariant kernel

The goal of this section is to prove Proposition 2.5. First, notice that $0 = w \cdot (\text{curl } K(w) \times w) = w \cdot \nabla J$, and hence J is a first integral of w . By the continuity of the kernel K , Proposition 2.5 follows if we show that J is a constant (a trivial first integral) on the manifold M for a residual (and hence dense) set of vector fields $w \in \mathfrak{X}_{ex}^k$.

To this end, consider the set \mathcal{R} of exact divergence-free vector fields $w \in \mathfrak{X}_{ex}^k$, whose zeros are hyperbolic (and hence isolated). Each vector field $w \in \mathcal{R}$ has finitely many zeros. This set was already introduced after the statement of Proposition 2.5, where it was pointed out that \mathcal{R} is an open and dense set of \mathfrak{X}_{ex}^k . The proof of Proposition 2.5 makes use of the following instrumental lemma.

Lemma 3.1. *If $w \in \mathcal{R}$ and P is a first integral of w of class C^{k-1} , $k \geq 4$, then any component of a regular level set of P is diffeomorphic to the torus \mathbb{T}^2 .*

Proof. By the assumption $k \geq 4$, Sard's theorem implies that most of the values of the first integral P are regular. Let $c \in \mathbb{R}$ be a regular value, then a connected component Σ_c of the level set $P^{-1}(c)$ is an oriented compact surface in M . Assume that Σ_c is diffeomorphic to a surface of genus $\nu \neq 1$, i.e., the surface is not a torus. The Poincaré-Hopf theorem easily implies that there exists a point $p_c \in \Sigma_c$ such that $w(p_c) = 0$ (and the index of w at p_c is nonzero). It follows from the compactness of the manifold that any value $c' \in (c - \delta, c + \delta)$, δ small enough, is regular as well. Moreover, Thom's isotopy theorem [1] implies that the level set $P^{-1}(c')$ is isotopic to $P^{-1}(c)$, and therefore there is a neighborhood of Σ_c that is saturated by components $\Sigma_{c'}$ of the level sets of P isotopic to Σ_c . Since on each surface $\Sigma_{c'}$, $c' \in (c - \delta, c + \delta)$, the field w vanishes at a point $p_{c'}$, we conclude that w has infinitely many zeros on M (in fact, a continuous arc of zeros). This contradicts the assumption that $w \in \mathcal{R}$, and therefore the genus of any component of a regular level set must be 1, i.e., it is diffeomorphic to a torus. \square

Take now a vector field $w_0 \in \mathcal{R} \subset \mathfrak{X}_{ex}^k$, and assume that the corresponding C^k function J_0 defined by Equation (4) is not a constant. Let $c \in \mathbb{R}$ be a regular value of J_0 (which exists by Sard's theorem). By Lemma 3.1, all the components of $J_0^{-1}(c)$ are diffeomorphic to a torus; in fact, there exists a domain $U \subset M$ which is trivially fibred by toroidal components of the level sets of J_0 (which are invariant tori of w_0), so in particular $U \cong \mathbb{T}^2 \times (0, 1)$. The following lemma shows that an arbitrarily small perturbation can destroy this trivial fibration of invariant tori.

Lemma 3.2. *For any $\epsilon > 0$, there exists a vector field $w \in \mathfrak{X}_{ex}^k$ such that $\|w - w_0\|_{C^k} < \epsilon$, $w = w_0$ on $M \setminus U$, and w does not admit a trivial fibration of invariant tori on U .*

Proof. The main idea of the proof is the following two-step procedure. First, we show that arbitrarily close to w_0 there is a field w_1 with a family of invariant tori, such that the winding number of trajectories on tori changes nondegenerately across the family. After that, by

choosing an invariant torus with a rational winding number p/q (which exists due to this nondegeneracy), we show that a generic perturbation of such a field w_1 leads to a field whose Poincaré return map has at least q hyperbolic saddles, and hence does not admit a fibration into invariant surfaces.

In more detail, by assumption, the domain $U \subset M$ is diffeomorphic to $\mathbb{T}^2 \times (0, 1)$ and each torus $\mathbb{T}^2 \times \{r\}$, $r \in (0, 1)$, is invariant under the flow of w_0 . Introduce the field $\xi := \nabla J_0 / (\nabla J_0)^2$. It is easy to check that the field $w_0|_{T_r}$ preserves the C^{k-1} area form

$$d\mu_2 := i_\xi d\mu \Big|_{T_r}, \quad (6)$$

since $T_r := \mathbb{T}^2 \times \{r\}$ corresponds to a regular level set of $J_0|_U$.

Let us introduce coordinates (θ_1, θ_2, r) parameterizing U , where $(\theta_1, \theta_2) \in \mathbb{T}^2 = (\mathbb{R}/2\pi\mathbb{Z})^2$ and $r \in (0, 1)$. Since w_0 preserves the area form $d\mu_2$ on each torus T_r , Sternberg's theorem [17] implies that the angular coordinates can be taken so that the vector field $w_0|_U$ in these coordinates reads as:

$$w_0 = F(\theta_1, \theta_2, r) \left(\Theta_1(r) \partial_{\theta_1} + \Theta_2(r) \partial_{\theta_2} \right),$$

where $\Theta_1(r)$, $\Theta_2(r)$ are C^k functions, and F is a nonvanishing C^{k-1} function.

Let us now perturb w_0 to obtain a vector field $w_1 \in \mathfrak{X}_{ex}^k$ such that $w_1 = w_0$ on $M \setminus U$, $\|w_1 - w_0\|_{C^k} < \delta$ for some δ that will be fixed later, and on U there are coordinates (that we still denote by (θ_1, θ_2, r)) such that

$$w_1 = \tilde{F}(\theta_1, \theta_2, r) \left(\tilde{\Theta}_1(r) \partial_{\theta_1} + \tilde{\Theta}_2(r) \partial_{\theta_2} \right),$$

where the C^{k-1} function \tilde{F} does not vanish on U , and the C^k functions $\tilde{\Theta}_1, \tilde{\Theta}_2$ satisfy on $(0, 1)$ that $\tilde{\Theta}_2$ has finitely many zeros and the ratio $\Phi(r) := \tilde{\Theta}_1 / \tilde{\Theta}_2$ is not identically constant. To prove that such a perturbation exists, it is enough to take a C^k vector field Q that is zero on $M \setminus U$, and on U is given in (θ_1, θ_2, r) -coordinates by

$$Q|_U := \frac{1}{h(\theta_1, \theta_2, r)} \left(f_1(r) \partial_{\theta_1} + f_2(r) \partial_{\theta_2} \right),$$

where h is the function that appears in the volume form when written in local coordinates, i.e. $d\mu = h d\theta_1 \wedge d\theta_2 \wedge dr$, and f_1, f_2 are C^k functions that are 0 in a neighborhood of $r = 0$ and $r = 1$, and $\|f_1\|_{C^k} < C\delta$, $\|f_2\|_{C^k} < C\delta$. It is straightforward to check that the field Q is divergence-free with respect to the volume $d\mu$, and it is exact because $i_Q d\mu = f_1(r) d\theta_2 \wedge dr - f_2(r) d\theta_1 \wedge dr$ is an exact 2-form on U , while $i_Q d\mu = 0$ on $M \setminus U$, so the field Q belongs to the space \mathfrak{X}_{ex}^k . Defining $w_1 := w_0 + Q$, a generic choice of the functions f_1 and f_2 gives the desired properties for w_1 .

The properties above allow us to take an interval $(a, b) \subset (0, 1)$ where $\tilde{\Theta}_2$ does not vanish and $\left| \frac{d}{dr} \Phi(r) \right| > 0$. The Poincaré return map of the vector field w_1 at the cross section $\mathbb{S}^1 \times \{\theta_2 = 0\} \times (a, b) \subset U$ is well defined and given by

$$\Pi(\theta_1, r) = \left(\theta_1 + 2\pi\Phi(r), r \right).$$

This is a C^k diffeomorphism of the annulus $\mathbb{S}^1 \times (a, b)$ that preserves an area form $d\sigma$ (which in these coordinates takes the form $f(r) d\theta_1 \wedge dr$ for some positive function f , but we will not use this specific form in what follows). Moreover, it satisfies the twist condition:

$$\left| \frac{d}{dr} \left(2\pi\Phi(r) \right) \right| > 0,$$

where $\Phi(r) = \tilde{\Theta}_1/\tilde{\Theta}_2$.

Let $c \in (a, b)$ be a value of the r -coordinate such that $2\pi\Phi(c) = p/q$ for some coprime natural numbers p and q . The circle $\{r = c\}$ is then formed by fixed points of the iterated map Π^q . The twist assumption implies that on the invariant circles $\{r < c\}$ and $\{r > c\}$ the map Π^q rotates in opposite directions. Take now a C^k diffeomorphism of the annulus $\Pi_\delta : \mathbb{S}^1 \times (a, b) \rightarrow \mathbb{S}^1 \times (a, b)$ which is $C\delta$ -close to Π , i.e. $\|\Pi_\delta - \Pi\|_{C^k} < C\delta$, preserves the area form $d\sigma$, and $\Pi_\delta = \Pi$ in a neighborhood of $\mathbb{S}^1 \times \{a\}$ and $\mathbb{S}^1 \times \{b\}$. The Poincaré-Birkhoff theorem [7, Section 4.8] shows that a generic perturbation Π_δ^q has at least q fixed points which are hyperbolic saddles and are $C\delta$ close to the circle $\{r = c\}$. These fixed points correspond to hyperbolic q -periodic points of the map Π_δ that bifurcate from the resonant circle $\{r = c\}$ as $\delta \rightarrow 0$.

To conclude the proof of the lemma, we now take the suspension of the diffeomorphism Π_δ along the θ_2 -direction to obtain a C^k vector field w_2 in the domain $V := \mathbb{T}^2 \times (a, b) \subset U$ whose Poincaré return map at the cross section $\mathbb{S}^1 \times \{\theta_2 = 0\} \times (a, b)$ is precisely Π_δ . Ref. [18] shows that this suspension can be taken such that w_2 is divergence-free with respect to the volume $d\mu$, $w_2 = w_1$ in a neighborhood of ∂V , and $\|w_2 - w_1\|_{C^k} < C\delta$. We can then define the vector field w on M as

$$w := \begin{cases} w_2 & \text{in } V, \\ w_1 & \text{in } M \setminus V. \end{cases}$$

It is obvious that w is C^k , divergence-free, and $\|w - w_0\|_{C^k} < \epsilon$ taking $\delta = \epsilon/C$. Moreover, we claim that it is exact. Indeed, since w_1 is exact, it is enough to show that the divergence-free field $R := w - w_1$ is also exact. This follows from the fact that R is supported on $V = \mathbb{T}^2 \times (a, b)$, which implies that $\int_{\mathbb{T}^2 \times \{r\}} i_R d\mu = 0$ for all $r \in (a, b)$; since any surface $\mathbb{T}^2 \times \{\cdot\}$ is a generator of the second homology group of V , we infer from De Rham's theorem that the closed 2-form $i_R d\mu$ is exact. Finally, notice that the properties of the map Π_δ proved above imply that w has (at least) a hyperbolic periodic orbit in the domain $V \subset U \subset M$, thus following that w cannot admit a trivial fibration by invariant tori on U . \square

We are now ready to prove Proposition 2.5. Take the vector field $w_0 \in \mathcal{R} \subset \mathfrak{X}_{ex}^k$ introduced before the statement of Lemma 3.2 that satisfies Equation (4) with some non-constant C^k function J_0 . As discussed above, there is a domain $U \subset M$ which is trivially fibred by toroidal components of the level sets of J_0 (which are invariant tori of w_0). For any $w \in \mathfrak{X}_{ex}^k$ as in the statement of Lemma 3.2, which is ϵ -close to w_0 , that is $\|w - w_0\|_{C^k} < \epsilon$, the function J defined by Equation (4) satisfies the estimate:

$$\|\nabla(J - J_0)\|_{C^{k-1}} = \|\text{curl } K(w) \times w - \text{curl } K(w_0) \times w_0\|_{C^{k-1}} < C\|w - w_0\|_{C^k},$$

where the constant C depends only on w_0 . Here we have used that the kernel $K : \mathfrak{X}_{ex}^k \rightarrow \mathfrak{X}_{ex}^k$ is continuous with respect to the C^k Whitney topology. Since the function J is defined up to a constant, the Poincaré inequality and this estimate imply that

$$\|J - J_0\|_{C^k} < C\epsilon.$$

It then follows from Thom's isotopy theorem [1] that the function J defines a trivial fibration by invariant tori of w in the domain U . However, this contradicts Lemma 3.2, which ensures that U is not trivially fibred by invariant tori of w .

We conclude that for any $w_0 \in \mathcal{R} \subset \mathfrak{X}_{ex}^k$, the corresponding first integral J_0 is a constant on M . The continuity properties of the kernel K and the density of the set \mathcal{R} readily imply that $\text{curl } K(w) \times w = 0$, for any $w \in \mathfrak{X}_{ex}^k$, as we desired to prove.

4 Adjoint and coadjoint invariants of volume-preserving diffeomorphisms

In this section we describe the geometry of the adjoint and coadjoint actions of the group of volume-preserving diffeomorphisms and prove Corollaries 1.2 and 1.3.

4.1 Invariants of the adjoint action on divergence-free vector fields and proof of Corollary 1.3

The Lie algebra of the group $\text{SDiff}(M)$ of (smooth) volume-preserving diffeomorphisms on a manifold M with a volume form $d\mu$ is the space \mathfrak{X} of all (smooth) divergence-free vector fields on M . The adjoint action of the Lie algebra on itself is by means of the Lie bracket of vector fields: given $v \in \mathfrak{X}$, the operator $\text{ad}_v : w \mapsto [w, v]$.

The divergence-free condition on a field w is equivalent to the condition that the 2-form $i_w d\mu$ is closed on M . A divergence-free vector field ξ on M is exact if the closed 2-form $i_\xi d\mu$ is exact. The space \mathfrak{X}_{ex} of all exact divergence-free vector fields on M is a Lie subalgebra of the Lie algebra \mathfrak{X} of all divergence-free vectors.

Note that ad_v leaves \mathfrak{X}_{ex} invariant. Indeed, for $w \in \mathfrak{X}_{ex}$ and $v \in \mathfrak{X}$ one has $i_w d\mu = d\alpha$ for a 1-form α , then

$$i_{[w,v]} d\mu = [i_w, L_v] d\mu = i_w(L_v d\mu) - L_v(i_w d\mu) = -L_v d\alpha = -dL_v \alpha,$$

i.e. $\text{ad}_v w = [w, v] \in \mathfrak{X}_{ex}$.

Furthermore, for any vector field $\xi \in \mathfrak{X}$ one can define its rotation class $\lambda(\xi) \in H_1(M, \mathbb{R})$ as follows, see [3]. Algebraically, $\lambda(\xi)$ is given by the cohomology class of the closed 2-form $i_\xi d\mu$ in $H^2(M, \mathbb{R})$, which is Poincaré isomorphic to $H_1(M, \mathbb{R})$. Equivalently, if the set of 1-forms $\{h_k\}_{k=1}^N$ is a basis of the first cohomology group of M , where N is the first Betti number of M , the rotation class $\lambda(\xi)$ is a vector in $\mathbb{R}^N \cong H_1(M, \mathbb{R})$ whose components are given by

$$(\lambda(\xi))_k = \int_M i_\xi d\mu \wedge h_k.$$

Geometrically, the rotation class is the averaging of asymptotic cycles defined by the trajectories of the field ξ : for any $x \in M$ take the trajectory $g_\xi^t(x)$ of the field ξ starting at $x = g_\xi^0(x)$ for time $t \in [0, T]$, and then close it up by a “short path” (e.g. a geodesic) between x and $g_\xi^T(x)$. This closed path defines an element $\lambda(\xi, x, T) \in H_1(M, \mathbb{R})$. Then $\lambda(\xi, x) := \lim_{T \rightarrow \infty} \lambda(\xi, x, T)/T \in H_1(M, \mathbb{R})$ is an asymptotic cycle associated with a point $x \in M$. It defines an element of $L^1(M)$ by the Birkhoff ergodic theorem, and one can prove that $\lambda(\xi) = \int_M \lambda(\xi, x) d\mu$, so both the algebraic and the geometric definitions of $\lambda(\xi)$ coincide, see [3].

Note that $\mathfrak{X}_{ex} = \{\xi \in \mathfrak{X} : \lambda(\xi) = 0\}$, i.e. exact divergence-free vector fields are exactly those having zero rotation class on M . Moreover, since any two closed 2-forms diffeomorphic via a diffeomorphism connected with the identity have the same rotation class, the group action of the connected component of the identity of $\text{SDiff}(M)$ (or the action of the Lie algebra \mathfrak{X}) preserves fibers of the projection $\lambda : \mathfrak{X} \rightarrow H_1(M, \mathbb{R})$. Helicity \mathcal{H} is then the only regular invariant on the zero fiber, $\mathfrak{X}_{ex} = \lambda^{-1}(0)$. Applying this consideration to vector fields of class C^k , $k \geq 4$, one proves Corollary 1.3.

Intuitively, the helicity value \mathcal{H} and the homology class $H_1(M, \mathbb{R})$ describe the full set of regular invariants. However, for non-zero fibers of the projection λ , only relative helicity between two different fields is well-defined, cf. [4].

4.2 Invariants of the coadjoint action and proof of Corollary 1.2

The dual of the Lie algebra \mathfrak{X} of all (smooth) divergence-free vector fields on M is isomorphic to the space $\mathfrak{X}^* = \Omega^1(M)/d\Omega^0(M)$ of all (smooth) 1-forms, modulo all exact 1-forms on M . The dual space to \mathfrak{X}_{ex} is the space $\mathfrak{X}_{ex}^* = \Omega^1(M)/Z^1(M)$ of all (smooth) 1-forms modulo all (smooth) closed 1-forms on M . The natural embedding $\mathfrak{X}_{ex} \subset \mathfrak{X}$ corresponds to the natural projection $\pi : \mathfrak{X}^* \rightarrow \mathfrak{X}_{ex}^*$, i.e. projections of cosets, $\pi : \Omega^1(M)/d\Omega^0(M) \rightarrow \Omega^1(M)/Z^1(M)$. The fibers of this projection are finite-dimensional and isomorphic to $Z^1(M)/d\Omega^0(M) = H^1(M, \mathbb{R})$.

There is an equivalent and simpler description of the dual space $\mathfrak{X}_{ex}^* = \Omega^1(M)/Z^1(M)$ as the space of exact 2-forms on M , by taking the differential of 1-forms: $\Omega^1(M)/Z^1(M) \cong d\Omega^1(M)$. For three-dimensional M with volume form $d\mu$, the space $\mathfrak{X}_{ex}^* = d\Omega^1(M)$ can also be identified with the space \mathfrak{X}_{ex} of exact divergence-free vector fields: an exact 2-form $d\alpha$ is associated with an exact field ξ by $i_\xi d\mu = d\alpha$. This is why one can consider both adjoint and coadjoint action on the space of exact vector fields on a three-dimensional manifold.

Remark 4.1. In more detail, to relate the vorticity fields $\xi = \text{curl } v$ and the corresponding cosets $[u]$ of 1-forms $u = v^\flat$, we introduce the operator $\sigma : \xi \mapsto [u]$ defined by $u := (\text{curl}^{-1}\xi)^\flat$, i.e. $\sigma = \mathbb{I} \circ \text{curl}^{-1}$. Here the map $\mathbb{I} : \mathfrak{X} \rightarrow \mathfrak{X}^* = \Omega^1(M)/d\Omega^0(M)$ is the inertia operator from the Lie algebra \mathfrak{X} of divergence-free vector fields to its dual: given a vector field v on a Riemannian manifold M , one defines the 1-form v^\flat as the pointwise inner product with the velocity field v , $v^\flat(w) := (v, w)$ for all $w \in T_x M$. Note that although both \mathbb{I} and curl^{-1} are metric dependent, the operator σ depends on the volume form $d\mu$ only, since ξ is the kernel of $d[u]$, i.e. $i_\xi d\mu = d[u] = d\sigma(\xi)$. The map σ gives the isomorphism between the spaces \mathfrak{X}_{ex} and \mathfrak{X}_{ex}^* .

Using this operator σ , one can identify the elements in \mathfrak{X}_{ex} and \mathfrak{X}_{ex}^* . The natural pairing $\langle \cdot, \cdot \rangle$ between \mathfrak{X}_{ex}^* and \mathfrak{X}_{ex} becomes

$$\langle \xi, v \rangle = \langle [u], v \rangle = \int_M \text{curl}^{-1}\xi \cdot v \, d\mu, \quad (7)$$

where $\xi \in \mathfrak{X}_{ex}$, $v \in \mathfrak{X}_{ex}$ and $[u] = \sigma(\xi) \in \mathfrak{X}_{ex}^*$.

By the identification of spaces \mathfrak{X}_{ex} and \mathfrak{X}_{ex}^* , one can introduce the coadjoint action on \mathfrak{X}_{ex} . We claim that the coadjoint operator ad_v^* on any exact divergence-free vector field ξ is given by the Lie bracket of two fields,

$$\text{ad}_v^* \xi = [\xi, v], \quad (8)$$

just like the adjoint action. Indeed, the action of ad_v^* is as follows: for any $v, w \in \mathfrak{X}(M)$ and $\xi \in \mathfrak{X}_{ex}(M)$, we have

$$\langle w, \text{ad}_v^* \xi \rangle = \langle w, \text{ad}_v^* \sigma(\xi) \rangle = \langle w, L_v \sigma(\xi) \rangle = \langle w, \sigma(L_v \xi) \rangle = \langle w, \sigma([\xi, v]) \rangle = \langle w, [\xi, v] \rangle. \quad (9)$$

The first equality is due to the identification of spaces \mathfrak{X}_{ex} and \mathfrak{X}_{ex}^* . (Abusing notations we use the same symbol ad^* for the corresponding fields and forms.) We also used here that the operator σ commutes with the volume-preserving changes of coordinates, and hence with L_v .

The above consideration is a manifestation of the fact that the adjoint and coadjoint actions of the group $\text{SDiff}(M)$ are geometric, i.e. they consist of the volume-preserving changes of coordinates. In the adjoint action one changes coordinates for a vector field. For the

coadjoint action one changes coordinates in the coset of 1-forms, or in the exact 2-form (the differential of the coset), or in the (vorticity) vector field, which is the kernel field, i.e. the exact divergence-free vector field naturally related to the 2-form.

To summarize, in the case of M with $H_1(M, \mathbb{R}) = 0$, one has the identifications $\mathfrak{X}^* \cong \mathfrak{X}_{ex}^* \cong \mathfrak{X}_{ex} \cong \mathfrak{X}$ with the Lie-bracket action, and hence all regular integral invariants on the dual space, i.e. all regular Casimirs, are functions of the helicity. This proves Corollary 1.2.

In the case of M with nontrivial $H_1(M, \mathbb{R})$, one has a natural projection $\pi : \mathfrak{X}^* \rightarrow \mathfrak{X}_{ex}^* = \mathfrak{X}_{ex}$. The helicity is well-defined for the image of this projection, i.e. for the vorticity field, and hence it has the same value for all fields in the same coset $[u] \in \mathfrak{X}^*$. But now the helicity cannot be the only invariant of the coadjoint action. For instance, take two different *closed* 1-forms u_1 and u_2 on M . For their cosets $[u_i] \in \mathfrak{X}^*$, $i = 1, 2$, one has $\pi([u_i]) = 0$, i.e. they belong to the zero fiber of this projection π . Their vorticity fields vanish, $\xi_i = 0$, since $du_i = 0$, and hence their helicity vanish as well, $\mathcal{H}(\xi_i) = 0$. On the other hand, the cohomology classes of u_i are elements of $H^1(M, \mathbb{R})$ and are invariant under coordinate transformations (in the identity connected component) of the group $\text{SDiff}(M)$.

Again, one expects that the helicity value \mathcal{H} and the cohomology class $H^1(M, \mathbb{R})$ describe the full set of regular invariants of the coadjoint action on \mathfrak{X}^* . Note, that the fibers of the projection $\pi : \mathfrak{X}^* \rightarrow \mathfrak{X}_{ex}$ (unlike the fibers for $\lambda : \mathfrak{X} \rightarrow H_1(M, \mathbb{R})$) are finite-dimensional: they are affine spaces isomorphic to $H^1(M, \mathbb{R})$. However, the cohomology class is well-defined only for the zero fiber of this projection, i.e. cosets $[u]$ of closed forms u .

5 Casimirs in 3D ideal and magnetic hydrodynamics

5.1 Geometry of the incompressible Euler equations

In [2] Arnold proved that the Lagrangian description of the Euler equations (1) can be regarded as the geodesic flow on the infinite-dimensional Lie group $\text{SDiff}(M)$ of volume-preserving diffeomorphisms of M with respect to a right-invariant L^2 -metric on the group. This geometric point of view implies the following Hamiltonian framework for ideal fluids.

Consider the (regular) dual space \mathfrak{X}^* to the space \mathfrak{X} of divergence-free vector fields on M , which is the Lie algebra of the group $\text{SDiff}(M)$. This dual space \mathfrak{X}^* is isomorphic to the space of cosets $\Omega^1(M)/d\Omega^0(M)$, where $\Omega^k(M)$ is the space of all smooth k -forms on M . An element in $\Omega^1(M)/d\Omega^0(M)$ is $[\alpha] = \{\alpha + df : \text{for all } f \in C^\infty(M)\}$. The natural pairing between the arbitrary elements $[\alpha] \in \mathfrak{X}^*$ and $v \in \mathfrak{X}$ is given by $\langle [\alpha], v \rangle := \int_M \alpha(u) d\mu$, where $d\mu$ is the volume form on the manifold M . The coadjoint action of the group $\text{SDiff}(M)$ on the dual \mathfrak{X}^* is given by the change of coordinates in (cosets of) 1-forms on M by means of volume-preserving diffeomorphisms.

Using the Riemannian metric (\cdot, \cdot) on the manifold M , one can identify the Lie algebra and its (regular) dual by means of the so-called inertia operator: given a vector field v on M one defines the 1-form v^\flat as the pointwise inner product with the velocity field v : $v^\flat(w) := (v, w)$ for all $w \in T_x M$. Note also that the 1-form v^\flat corresponding to a divergence-free field v is co-closed. Then the Euler equations (1) can be rewritten on 1-forms $\alpha = v^\flat$ as $\partial_t \alpha + L_v \alpha = -dP$ for an appropriate function P on M , which is not the pressure (see [4, 16]).

In terms of the cosets of 1-forms $[\alpha]$, the Euler equations assume the form

$$\partial_t [\alpha] + L_v [\alpha] = 0 \tag{10}$$

on the dual space \mathfrak{X}^* . Equation (10) on \mathfrak{X}^* turns out to be Hamiltonian with respect to the natural linear Lie-Poisson bracket on the dual space and the Hamiltonian functional H given

by the kinetic energy of the fluid, $H([\alpha]) = \frac{1}{2} \int_M (v, v) d\mu$ for $\alpha = v^\flat$, see details in [2, 4]. The corresponding Hamiltonian operator is given by the Lie algebra coadjoint action ad_v^* , which in the case of the diffeomorphism group corresponds to the Lie derivative: $\text{ad}_v^* = L_v$. Its symplectic leaves are coadjoint orbits of the corresponding group $\text{SDiff}(M)$.

All invariants of the coadjoint action, also called *Casimir functions*, are first integrals of the Euler equations for any choice of the Riemannian metric (with a fixed volume form). Theorem 1.1 shows that the helicity is the only C^1 (continuously differentiable) Casimir function for the coadjoint action of the volume-preserving diffeomorphism group $\text{SDiff}(M)$ on exact divergence-free vector fields. In the particular case that the first homology group of M is trivial, this corresponds to the coadjoint action of $\text{SDiff}(M)$ on the whole dual space \mathfrak{X}^* of the Lie algebra \mathfrak{X} (see Section 4 for details).

5.2 Magnetic- and cross-helicity in magnetohydrodynamics

Combining Theorem 1.1 with the results of [9] one can describe regular invariants for magnetohydrodynamics (MHD). Recall that the MHD equations on a closed three-dimensional Riemannian manifold M describe the motion of an infinitely conducting ideal fluid of velocity v carrying a magnetic field B :

$$\begin{cases} \partial_t v = -\nabla_v v + (\text{curl } B) \times B - \nabla p, \\ \partial_t B = -[v, B], \\ \text{div } B = \text{div } v = 0. \end{cases} \quad (11)$$

Here $[v, B]$ stands for the Lie bracket of the vector fields v and B , and \times denotes the cross product on M .

Consider the space $\mathfrak{X}_{ex}^k \times \mathfrak{X}_{ex}^k$ of pairs (ω, B) of vorticity and magnetic fields on the manifold M . Then the *magnetic helicity* is defined as

$$\mathcal{H}(B) := \int_M B \cdot \text{curl}^{-1} B d\mu,$$

while the *cross-helicity* is

$$\mathcal{H}(\omega, B) := \int_M B \cdot \text{curl}^{-1} \omega d\mu = \int_M B \cdot v d\mu,$$

where $\omega = \text{curl } v$ on M (in other words, v is the only field in \mathfrak{X}_{ex}^k such that $\text{curl } v = \omega$).

It is well known [4] that both the magnetic helicity $\mathcal{H}(B)$ and the cross-helicity $\mathcal{H}(\omega, B)$ are first integrals of the MHD equations. Furthermore, they are Casimirs of the MHD equations, i.e., they are invariants of the coadjoint action of the semidirect-product group $G = \text{SDiff}(M) \ltimes \mathfrak{X}^*$ on the dual space of its Lie algebra.

One can introduce the notion of a regular integral invariant $\mathcal{F} : \mathfrak{X}_{ex}^k \times \mathfrak{X}_{ex}^k \rightarrow \mathbb{R}$ similar to Definition 2.2, see details in [9]. Theorem 1.1 has the following MHD analogue, proved *mutatis mutandis*.

Theorem 5.1. *Let \mathcal{F} be a regular integral invariant on $\mathfrak{X}_{ex}^k \times \mathfrak{X}_{ex}^k$, then \mathcal{F} is a function of the magnetic helicity and the cross-helicity provided that $k \geq 4$ (this includes the case $k = \infty$). More precisely, a C^1 function $f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ exists such that $\mathcal{F}(\omega, B) = f(\mathcal{H}(B), \mathcal{H}(\omega, B))$, where $(\omega, B) \in \mathfrak{X}_{ex}^k \times \mathfrak{X}_{ex}^k$.*
