THE LENGTH OF A SHORTEST CLOSED GEODESIC
AND THE AREA OF A 2-DIMENSIONAL SPHERE

R. ROTMAN

(Communicated by Jon G. Wolfson)

ABSTRACT. Let $M$ be a Riemannian manifold homeomorphic to $S^2$. The purpose of this paper is to establish the new inequality for the length of a shortest closed geodesic, $l(M)$, in terms of the area $A$ of $M$. This result improves previously known inequalities by C.B. Croke (1988), by A. Nabutovsky and the author (2002) and by S. Sabourau (2004).

Let $l(M)$ denote the length of a shortest closed non-trivial geodesic on a closed Riemannian manifold $M$ and let $A$ be the area of $M$. In this paper we will prove the following theorem.

**Theorem 0.1.** Let $M$ be a manifold diffeomorphic to the 2-dimensional sphere. Then $l(M) \leq 4\sqrt{2A}$.

The first upper bounds for the length of a shortest closed geodesic on a 2-dimensional sphere were found by C.B. Croke (see [2]). In his paper Croke found estimates both in terms of the diameter and in terms of the area of a 2-dimensional sphere. Those results were later improved in [5] and in [9]. In particular, Croke proved that $l(M) \leq 31\sqrt{A}$, Sabourau proved that $l(M) \leq 12\sqrt{A}$, and A. Nabutovsky and the author proved that $l(M) \leq 8\sqrt{A}$, which was the best known estimate prior to this paper.

The estimate that we will obtain in this paper is not sharp. We are aware of only three sharp bounds for the length of a shortest closed geodesic in terms of the area. These results are due to K. Loewner, in the case when $M$ is diffeomorphic to the 2-dimensional torus, to P. Pu in the case of $M$ being diffeomorphic to $RP^2$ and to C. Bavard, in the case when $M$ is diffeomorphic to the Klein bottle (see [3]).

It was suggested by E. Calabi and C.B. Croke that the sharp bound for the length of a shortest closed geodesic on a manifold diffeomorphic to $S^2$ should be $l(M) < 12\sqrt{A}$. (It is not hard to see that the optimal constant is at least $12\frac{1}{2}$; see [2].)

The existence of a closed geodesic on an arbitrary closed Riemannian manifold was proven by L. Lusternik and A. Fet (see [1]). Their proof uses Morse theory on the space $\Lambda M$ of closed curves on $M$. One approach to estimating the length of a shortest closed geodesic can be interpreted as effectivization of this existence theorem. In particular, this approach is used in papers [2], [6].
The classical proof of the Lusternik and Fet theorem suggests that in order to estimate the length of a shortest closed geodesic it is enough to construct a non-contractible map \( f : S^1 \rightarrow \Lambda_L M \), where \( \Lambda_L M \) is the space of closed continuous curves on \( M \) of length bounded from above by \( L \).

However, in this paper, as in [5], we will replace the space \( \Lambda_L M \) with the space \( \Gamma \) of parametrized 1-cycles made of two segments. In fact, this paper closely follows the proof of Theorem 2 of [5].

The space \( \Gamma \) was introduced by E. Calabi and J. Cao. It is defined as follows:

\[
\Gamma = \{ \Phi | \Phi = (\phi_1, \phi_2), \phi_i : [0, 1] \rightarrow S^2 \text{ is a piecewise smooth path and } \phi_1(1) + \phi_2(1) - \phi_1(0) - \phi_2(0) = 0 \}; \text{ see (4)}.
\]

They defined the length functional on \( \Gamma \) by letting \( L(\Phi) = L(\phi_1) + L(\phi_2) \). They further defined a distance on \( \Gamma \) that makes \( L \) into a continuous map.

The critical points of \( L \) on \( \Gamma \) are defined as in geometric measure theory: Let \( \chi(M) \) denote the set of all smooth vector fields on \( M \). Any \( X \in \chi(M) \) generates a one-parameter group of diffeomorphisms \( h_t \). The derivation of \( L \) at \( \phi \in \Gamma \) in the direction of \( X \) is defined by \( \delta L(\phi)(X) = \frac{d}{dt}(L(h_t \circ \phi)) |_{t=0} \). If \( \delta L(\phi)(X) = 0 \) for all \( X \in \chi(M) \), then \( \Phi \) is called a critical point of \( L \) on \( \Gamma \) and \( L(\Phi) \) is called a critical value of \( L \).

Following J. Pitts, E. Calabi and J. Cao observed that critical points of \( L \) in \( \Gamma \), in the case when \( M \) is diffeomorphic to \( S^2 \), satisfy the property that both of the segments together form either a single closed geodesic, or a pair of closed geodesics, if we assume that both of the segments are smooth. Note, that without this assumption, the conclusion would be false.

Indeed, applying the first variational formula for the length functional, it is easy to see that any critical point of \( L \) on any Riemannian manifold is either a closed geodesic (possibly a constant geodesic), a pair of closed geodesics, or two geodesic loops emanating from the same point. In the last case the sum of four unit tangent vectors at the singular point coming out of this point must be zero. If the manifold is two-dimensional this implies that these two-geodesic loops form a self-intersecting closed geodesic.

Finally, Calabi and Cao note that if \( f : S^1 \rightarrow \Gamma \) is non-contractible, then there exists a closed geodesic on \( M \) of length \( \leq \max_{t \in S^1} \text{length}(f(t)) \) (see also Proposition 5 in [7] for a rigorous proof of this assertion).

So, the approach that we will use here is to construct a non-contractible \( f : S^1 \rightarrow \Gamma \) corresponding to the fundamental homology class of \( M \) and to estimate \( \max_{t \in S^1} L(f(t)) \). Using this approach, we have established in [5] that \( l(M) \leq 4d \).

We will use this result in this paper.

We will improve the technique used in [2] by Croke to obtain a bound for \( l(M) \) in terms of the area of \( M \). We will need the following definition from [2].

**Definition 0.2.** Let \( \gamma \) be a simple closed curve on \( M \) dividing \( M \) into two components. Then \( \gamma \) will be called convex to \( \Omega \), where \( \Omega \) is one of those components if there exists an \( \epsilon > 0 \) such that for all \( x, y \in \gamma \), satisfying \( d(x, y) < \epsilon \), the minimizing geodesic \( \tau \) from \( x \) to \( y \) lies in the closure of \( \Omega \).

Lemma 2.2 in [2] asserts that if \( \gamma \) is convex to \( \Omega \) and \( \bar{\Omega} \) is compact, then there exists a “large enough” \( N \) such that if we apply Birkhoff curve shortening process with \( N \) breaks to \( \gamma \), then all curves in the resulting homotopy \( \gamma_t \) stay in \( \bar{\Omega} \), or to
Proof. The notation that will be encountered in this proof is borrowed from the proof of Theorem 2 in [5]. Let us begin by assuming that $l_\alpha$ be more exact, they satisfy the following two conditions:

1. $\gamma_t \in \Omega$.
2. $\gamma_t$ is simple and convex to $\Omega = \Omega - \{x \in \gamma_s | 0 \leq s \leq t\}$.

Therefore, assuming there are no geodesics in $M$ of length $\leq \text{length}(\gamma)$, and $\gamma = \partial \Omega$ is convex to $\Omega$, $\gamma$ can be contracted inside $\Omega$ by a homotopy that passes through closed curves of length $\leq \text{length}(\gamma)$.

We are now ready to prove Theorem 0.1.

**Step 1.** Let $x, y \in M$ be two points that are a diameter apart, that is, $d(x, y) = d$. Let $\alpha(t)$ be a minimal geodesic joining $x$ and $y$ parametrized proportionally to its arclength. Then either

1. For some $t \in (\frac{\sqrt{2A}}{2}, d - \frac{\sqrt{2A}}{2})$ there exist two geodesic loops $\gamma_x$ and $\gamma_y$ of length $\leq \sqrt{2A}$ based at $\alpha(t)$ and intersecting only at that point, such that $\gamma_x$ separates $M$ into two domains: $\Omega$ and its complement, where $x \in \Omega$ and $\gamma_x$ is convex to $\Omega$; $\gamma_y$ separates $M$ into two domains: $\Omega_y$ and its complement, where $y \in \Omega_y$ and $\gamma_y$ is convex to $\Omega_y$. Moreover $\Omega_x \cap \Omega_y = \emptyset$, and $\gamma_x = -\gamma_y$ is convex to the complement of $\Omega_x \cup \Omega_y$ in $M$; see Figure 1(a), (b).

or (2) There exists a simple closed geodesic loop $\gamma$ of length $\leq \sqrt{2A}$ not contractible in $M - \{x, y\}$ separating $M$ into two domains $\Omega_x$ and $\Omega_y$ such that $x \in \Omega_x$ and $y \in \Omega_y$, and either $\gamma$ is based at $\alpha(\frac{\sqrt{2A}}{2})$ and is convex to $\Omega_y$, or $\gamma$ is based at $\alpha(d - \frac{\sqrt{2A}}{2})$ and is convex to $\Omega_x$. Moreover, (a) $\gamma$ intersects $\alpha$ only at its base point; and (b) the tangent vectors to $\gamma$ at its beginning and end lie on opposite sides of the straight line tangent to $\alpha$ in the tangent plane of $M$ at the base point of $\gamma$; see Figure 2(a).

The following proof of the above statement is an improvement of the proof of the similar fact in [2].

Let $t_0$ be any number in the interval $(\frac{\sqrt{2A}}{2}, d - \frac{\sqrt{2A}}{2})$.

We will begin by showing that there exists a simple closed geodesic loop based at $\alpha(t_0)$ that divides $M$ into two domains, one containing $x$ and the other containing $y$. In order to prove this take the geodesic spheres $S(x, t)$ in $M$ centered at $x$ of radius $t$ for all $t \in [t_0 - \frac{\sqrt{2A}}{2}, t_0 + \frac{\sqrt{2A}}{2}]$.

Note that for any generic $t$ there exists a closed curve $\sigma \subset S(x, t)$ with no self-intersections that intersects $\alpha$ transversally at $\alpha(t)$, and this intersection with $\alpha$ is unique. Now, compare the inequality $\int_{t_0 - \frac{\sqrt{2A}}{2}}^{t_0 + \frac{\sqrt{2A}}{2}} \text{length}(S(x, t))dt < A$ and the equality $\int_{t_0 - \frac{\sqrt{2A}}{2}}^{t_0 + \frac{\sqrt{2A}}{2}} \sqrt{2A} - 2|t - t_0|dt = A$. They imply that there exists a generic $t_\ast \in [t_0 - \frac{\sqrt{2A}}{2}, t_0 + \frac{\sqrt{2A}}{2}]$ such that the length of $S(x, t)$ is less than $\sqrt{2A} - 2|t - t_0|$. The same inequality will hold for $\sigma$, which, by Jordan Separation theorem, divides $M$ into two domains. Moreover, one of them will contain $x$ and another will contain $y$. Next consider a loop based at $\alpha(t_0)$ that goes to $\alpha(t_\ast)$ along $\alpha$, then along $\sigma$, and then back to $\alpha(t_0)$. This loop will be the desired $\gamma$. The proof is complete.
and finally returns to $\alpha(t_0)$ along $\alpha$. This curve is not contractible in $M \setminus \{x, y\}$ (see the proof of Lemma 3.2(1) in [2]), and it has length smaller than $\sqrt{2A}$.

This implies that the length of a shortest closed curve passing through $\alpha(t_0)$ and not contractible in $M \setminus \{x, y\}$ is also less than $\sqrt{2A}$. This shortest curve exists (though it does not have to be unique), and is in fact a geodesic loop based at $\gamma(t_0)$. If $\rho_{t_0}$ is such a geodesic loop, it is a simple curve dividing two domains $M_x$ and $M_y$, such that $x \in M_x$ and $y \in M_y$. The fact that this curve is the shortest among curves satisfying the above properties implies that it has no self intersections, which in turn implies that it divides $M$ into two domains (see also the proof of Lemma 3.3 in [2]). Such a curve will also have the following property: the two tangents at its endpoints will lie on opposite sides of the tangent to $\alpha$, otherwise could homotop this curve into $M - \alpha([0, 1])$ and contract it there (see the proof of Lemma 3.3(2) in [2]).

Note that, being a geodesic loop, $\rho_{t_0}$ is convex to one of these domains. Following [2] let $S_x$ denote the subset of $(\sqrt{\frac{A}{2}}, d - \sqrt{\frac{A}{2}})$ formed by $t_0$ such that there exists such a $\rho_{t_0}$ which is convex to $M_x$. One can similarly define $S_y$. Both $S_x$ and $S_y$ are closed subsets of $(\sqrt{\frac{A}{2}}, d - \sqrt{\frac{A}{2}})$. If both of these sets are non-empty, then their intersection is non-empty, and thus there exists $t_0 \in (\sqrt{\frac{A}{2}}, d - \sqrt{\frac{A}{2}})$ and two geodesic loops $\gamma_x$, $\gamma_y$ based at $\alpha(t_0)$ of equal length that is smaller than $\sqrt{2A}$ as in case (1) above. Note that $\gamma_x$ and $\gamma_y$ will intersect only at their base point (see the proof of Lemma 3.3(3) in [2]). If one of these two sets, for example, $S_x$, is empty, then for any $t_0 \in (\sqrt{\frac{A}{2}}, d - \sqrt{\frac{A}{2}})$, $\rho_{t_0}$ will be convex to $M_y$. It is easy to see that when $t_0 \rightarrow \frac{\sqrt{A}}{2}$ a subsequence of $\rho_{t_0}$ converges to a geodesic loop $\gamma$ of length $\leq \sqrt{2A}$ based at $\alpha(\frac{\sqrt{A}}{2})$, as in case (2). (One needs to be a little careful about the case when the length of $\gamma$ is exactly $\sqrt{2A}$. Indeed, if $\gamma$ passes through $x$ it consists of two minimizing geodesics between $\alpha(\frac{\sqrt{A}}{2})$ and $x$ such that the angle between them at $x$ is equal to $\pi$. But this cannot happen because since $\alpha$ minimizes past $\alpha(\frac{\sqrt{A}}{2})$, the segment of $\alpha$ between $x$ and $\alpha(\frac{\sqrt{A}}{2})$ is the unique minimizing geodesic between these points.)

**Step 2.** We are now ready to finish the proof of this theorem. Let us first consider case (1). We have subdivided the manifold into three domains: $\Omega_x, \Omega_y$ and $\Omega$, which denote the complement of $\Omega_x \cup \Omega_y$. We have assumed that $l(M) > 3\sqrt{2A} > \sqrt{2A}$. Therefore, $\gamma_x$ is contractible in $\Omega_x$ to $p_x \in \Omega_x$ along the curves $\gamma_{x_t}$, $\gamma_y$ is contractible in $\Omega_y$ to a point $p_y \in \Omega_y$ along the curves $\gamma_{y_t}$ of length $\leq \sqrt{2A}$, and $\gamma_x \cup -\gamma_y$ is contractible to $p$ in $\Omega$ along the curves $\gamma_t$ of length $\leq 2\sqrt{2A}$, since this curve is convex to $\Omega$.

We can now construct $f : S^1 \rightarrow \Gamma$, so that $S^1$ passes through pairs of curves of length $\leq 2\sqrt{2A}$ as shown on Figure 1: We begin with pairs of constant curves $(p_x \cup p_y)$ (Figure 1(b)), which is homotopic to a pair of curves $(\gamma_{x_t} \cup -\gamma_{y_t})$ (Figure 1(c)). These maps are homotopic to the “figure 8” $\gamma_x \cup -\gamma_y$ (Figure 1(d)), which we can finally connect with $p$ (Figure 1(f)) along the curves $\gamma_t$ (Figure 1(e)). Note that $p \sim (p_y \cup p_y)$, and, thus, we have formed a loop in the space of the parametrized 1-cycles. Moreover, this loop is not contractible (the proof of Theorem 2 in [5] contains the proof of a similar statement).
One can calculate that the total length of curves in the homotopy is bounded from above by $2\sqrt{2}A$.

In case (2), assume without loss of generality that there exists a simple closed geodesic loop $\gamma$ of length $\leq \sqrt{2}A$ that is not contractible in $M - \{x, y\}$ based at $\alpha(\sqrt{2}A^2)$ and that is convex to $\Omega_y$.

Following [2] we use Berger’s lemma. It implies the existence of minimizing geodesics $\alpha_1, \alpha_2$ joining points $x, y$ such that $\alpha_1'(0), \alpha_2'(0), \alpha'(0)$ do not lie in an open half plane. (It is possible that $\alpha_1 = \alpha_2$.)

Let $a, b, c$ denote the unique points of intersection of $\gamma$ with $\alpha, \alpha_1, \alpha_2$, respectively. (Having more than one point of intersection would contradict the minimality of $\gamma$; see the proof of Theorem 4.2 in [2]). It follows that (1) the length of a geodesic segment joining $x$ and $a$ and denoted $\alpha_{xa}$ equals $\sqrt{2}A$ by assumption; (2) the length of a geodesic segment joining $x$ and $b$ and denoted $\alpha_{xb}$ is $\leq \sqrt{2}A$; (3) the length of a geodesic segment $\alpha_{xc}$ that connects $x$ and $c$ is $\leq \sqrt{2}A$.

Let us further denote the segments of $\gamma$ that connect $a$ and $c$, $c$ and $b$ and $b$ and $a$ as $\gamma_{ac}, \gamma_{cb}$ and $\gamma_{ba}$, respectively.

Since $\ell(M) > 3\sqrt{2}A$ and since the closed curve $\beta_1 = \alpha_{xa} \cup -\gamma_{ba} \cup -\alpha_{xb}$ is convex to $\Omega_1$, it is contractible in $\Omega_1$ to a point $p_1$ along the curves $\beta_{1t}$. Its length does not increase during this homotopy.

Similarly, $\beta_2 = \alpha_{xa} \cup \gamma_{ac} \cup -\alpha_{xc}$ is contractible in $\Omega_2$ to a point $p_2$ along the curves $\beta_{2t}, \beta_3 = -\alpha_{xc} \cup \alpha_{xb} \cup -\gamma_{cb}$ is contractible in $\Omega_3$ to a point $p_3$ along the curves $\beta_{3t}$, and $\gamma$ is contractible in the complement of $\Omega_1 \cup \Omega_2 \cup \Omega_3$ along the curves $\gamma_t$ without the length increase (see Figure 2(a)).

We are now ready to construct $f : S^1 \rightarrow \Gamma$:

(1) $(p_1 \cup p_2) \sim (-\beta_1 \cup \beta_2)$ (see Figure 2(b)-(d)).
(2) \((-\beta_1 \cup \beta_2) \sim (\alpha_{xb} \cup \gamma_{ba} \cup \gamma_{ac} \cup -\alpha_{xc}) = \beta_4\) (see Figure 2(d)-(f)).

(3) \(\beta_4 \sim (\beta_3 \cup \gamma)\) (see Figure 2(f)-(h)).

(4) Finally, \((\beta_3 \cup \gamma) \sim (p_3 \cup p_4) \sim (p_1 \cup p_2)\).

Note that the length of curves during this homotopy is \(\leq 4\sqrt{2}A\).

It remains to check that this homotopy corresponds to a non-contractible map of \(S^1\) to the space \(\Gamma\). This argument is identical to the similar argument in \[5\]. □
