Abstract. I will define “meta-groups” and explain how one specific meta-group, which in itself is a “meta-bicrossed-product”, gives rise to an “ultimate Alexander invariant” of tangles, that contains the Alexander polynomial (multivariable, if you wish), has extremely good composition properties, is evaluated in a topologically meaningful way, and is least-wasteful in a computational sense. If you believe in categorification, that’s a wonderful playground.

This work is closely related to work by Le Dimet (Comment. Math. Helv. **67** (1992) 306–315), Kirk, Livingston and Wang (arXiv:math/9806035) and Cimasoni and Turaev (arXiv:math.GT/0406269).

Alexander Issues.

- Quick to compute, but computation departs from topology.
- Extends to tangles, but at an exponential cost.
- Hard to categorify.

Idea. Given a group G and two “YB” pairs $R^\pm = (g_o^\pm, g_u^\pm) \in G^2$, map them to xings and “multiply along”, so that

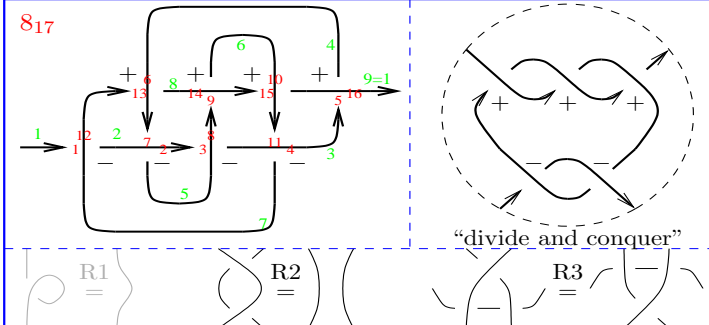

This Fails! R2 implies that $g_o^\pm g_o^\mp = e = g_u^\pm g_u^\mp$ and then R3 implies that g_o^+ and g_u^+ commute, so the result is a simple counting invariant.

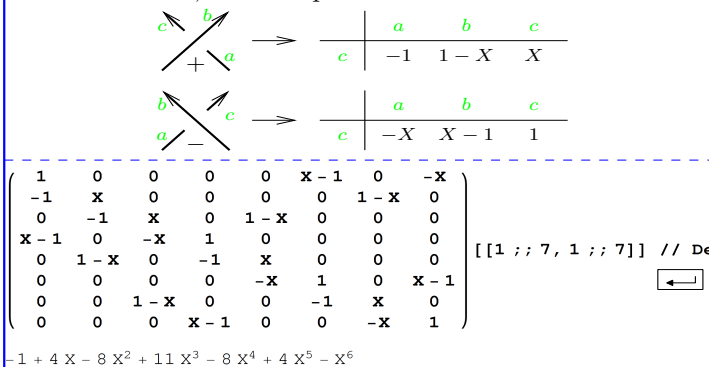

A Group Computer. Given G , can store group elements and perform operations on them:

Also has S_x for inversion, e_x for unit insertion, d_x for register deletion, Δ_{xy}^z for element cloning, ρ_y^x for renamings, and $(D_1, D_2) \mapsto D_1 \cup D_2$ for merging, and many obvious composition axioms relating those.

$$P = \{x : g_1, y : g_2\} \Rightarrow P = \{d_y P\} \cup \{d_x P\}$$

A Standard Alexander Formula. Label the arcs 1 through $(n+1) = 1$, make an $n \times n$ matrix as below, delete one row and one column, and compute the determinant:

A Meta-Group. Is a similar “computer”, only its internal structure is unknown to us. Namely it is a collection of sets $\{G_\gamma\}$ indexed by all finite sets γ , and a collection of operations m_z^{xy} , S_x , e_x , d_x , Δ_{xy}^z (sometimes), ρ_y^x , and \cup , satisfying the exact same *linear* properties.

Example 0. The non-meta example, $G_\gamma := G^\gamma$.

Example 1. $G_\gamma := M_{\gamma \times \gamma}(\mathbb{Z})$, with simultaneous row and column operations, and “block diagonal” merges. Here if $P = \begin{pmatrix} x & a & b \\ y & c & d \end{pmatrix}$ then $d_y P = (x : a)$ and $d_x P = (y : d)$ so $\{d_y P\} \cup \{d_x P\} = \begin{pmatrix} x & a & 0 \\ y & 0 & d \end{pmatrix} \neq P$. So this G is truly meta.

Claim. From a meta-group G and YB elements $R^\pm \in G_2$ we can construct a knot/tangle invariant.

Bicrossed Products. If $G = HT$ is a group presented as a product of two of its subgroups, with $H \cap T = \{e\}$, then also $G = TH$ and G is determined by H , T , and the “swap” map $sw^{th} : (t, h) \mapsto (h', t')$ defined by $th = h't'$. The map sw satisfies (1) and (2) below; conversely, if $sw : T \times H \rightarrow H \times T$ satisfies (1) and (2) (+ lesser conditions), then (3) defines a group structure on $H \times T$, the “bicrossed product”.
