OLYMON

Produced by the Canadian Mathematical Society and the Department of Mathematics of the University of Toronto.

Issue 10:3

March, 2009

Please send your solutions to
Rosu Mihai
54 Judith Crescent
Brampton, ON L6S 3J4

no later than April 15, 2009. Electronic files can be sent to rosumihai@yahoo.ca. However, please do not send scanned files; they use a lot of computer space, are often indistinct and can be difficult to download.

It is important that your complete mailing address and your email address appear legibly on the front page. If you do not write your family name last, please underline it.

Problems for March, 2009

605. Prove that the number 299 \ldots 998200 \ldots 029 can be written as the sum of three perfect squares of three consecutive numbers, where there are \( n - 1 \) nines between the first 2 and the 8, and \( n - 2 \) zeros between the last pair of twos.

606. Let \( x_1 = 1 \) and let \( x_{n+1} = \sqrt{x_n^2 + n^2} \) for each positive integer \( n \). Prove that the sequence \( \{x_n : n > 1\} \) consists solely of irrational numbers and calculate \( \sum_{k=1}^{n} \lfloor x_n^2 \rfloor \), where \( \lfloor x \rfloor \) is the largest integer that does not exceed \( x \).

607. Solve the equation
\[
\sin x \left( 1 + \tan x \tan \frac{x}{2} \right) = 4 - \cot x.
\]

608. Find all positive integers \( n \) for which \( n, n^2 + 1 \) and \( n^3 + 3 \) are simultaneously prime.

609. The first term of an arithmetic progression is 1 and the sum of the first nine terms is equal to 369. The first and ninth terms of the arithmetic progression coincide respectively with the first and ninth terms of a geometric progression. Find the sum of the first twenty terms of the geometric progression.

610. Solve the system of equations
\[
\log_{10}(x^3 - x^2) = \log_5 y^2
\]
\[
\log_{10}(y^3 - y^2) = \log_5 z^2
\]
\[
\log_{10}(z^3 - z^2) = \log_5 x^2
\]

where \( x, y, z > 1 \).

611. The triangle \( ABC \) is isosceles with \( AB = AC \) and \( I \) and \( O \) are the respective centres of its inscribed and circumscribed circles. If \( D \) is a point on \( AC \) for which \( ID \parallel AB \), prove that \( CI \perp OD \).

Challenge problems

The following problems are ones for which I do not have a solution. You are invited to solve them and send in your solution as early as you can. The first four problems posed last month have been solved, but
I am still open to receiving further solutions. They will be posed at part of a future Olymon and I will acknowledge the solvers then.

C5. Solve the equation

\[ x^{12} - x^9 + x^4 - x = 1. \]

C6. Suppose that \( n > 1 \) and that \( S \) is the set of all polynomials of the form

\[ z^n + a_{n-1}z^{n-1} + a_{n-2}z^{n-2} + \cdots + a_1z + a_0, \]

whose coefficients are complex numbers. Determine the minimum value over all such polynomials of the maximum value of \(|p(z)|\) when \(|z| = 1\).

C7. Let \( a_1, a_2, \ldots, a_n \) be distinct integers. Prove that the polynomial

\[ p(z) = (z - a_1)^2(z - a_2)^2\cdots(z - a_n)^2 + 1 \]

cannot be written as the product of two nonconstant polynomials with integer coefficients.

C8. Determine the locus of one focus of an ellipse reflected in a variable tangent to the ellipse.

C9. Let \( I \) be the centre of the inscribed circle of a triangle \( ABC \) and let \( u, v, w \) be the respective lengths of \( IA, IB, IC \). Let \( P \) be any point in the plane and \( p, q, r \) the respective lengths of \( PA, PB, PC \). Prove that, with the sidelengths of the triangle given conventionally as \( a, b, c \),

\[ ap^2 + bq^2 + cr^2 = au^2 + bv^2 + cu^2 + (a + b + c)z^2, \]

where \( z \) is the length of \( IP \).

Solutions.

591. The point \( O \) is arbitrarily selected from the interior of the angle \( KAM \). A line \( g \) is constructed through the point \( O \), intersecting the ray \( AK \) at the point \( B \) and the ray \( AM \) at the point \( C \). Prove that the value of the expression

\[ \frac{1}{|AOB|} + \frac{1}{|AOC|} \]

does not depend on the choice of the line \( g \). [Note: \([MNP]\) denotes the area of triangle \( MNP \).]

Solution 1. Construct a line passing through the point \( O \) and parallel to \( AC \). Let this line intersect the line \( AB \) at the point \( P \). Taking note that two triangles having their bases on a line and their third vertex on a parallel line have areas in proportion to their bases, we obtain that

\[ \frac{1}{|AOB|} + \frac{1}{|AOC|} = \frac{|AOB| + |AOC|}{|AOB||AOC|} = \frac{|ABC|}{|AOB||AOC|}, \]

\[ = \frac{|ABC|}{|AOB||AOC|} \cdot \frac{|APO|}{|APO|} = \frac{|ABC|}{|AOC|} \cdot \frac{|APO|}{|APO|} = \frac{1}{|AOC|} \cdot \frac{|APO|}{|APO|} = \frac{1}{|ACO|} \cdot \frac{|APO|}{|APO|}, \]

Since none of the points \( A, P, O \) depend on the position of the line \( g \), the desired result follows.

Solution 2. Let \( a = |AO|, b = |AB|, c = |AC|, \beta = \angle BAO, \gamma = \angle CAO \) and \( \theta = \angle AOB \). The distance from \( O \) to \( AB \) is \( a \sin \beta \) and from \( O \) to \( AC \) is \( a \sin \gamma \). Therefore, \([AOB] = \frac{1}{2}ba \tan \beta \) and \([AOC] = \frac{1}{2}ca \tan \gamma \). Note that \( \angle ABO = 180^\circ - (\theta + \beta) \) and \( \angle ACO = \theta - \gamma \), so that, by the Law of Sines,

\[ b = \frac{a \sin \theta}{\sin(\theta + \beta)} \quad \text{and} \quad c = \frac{a \sin \theta}{\sin(\theta - \gamma)}. \]
Therefore
\[
\frac{1}{[AOB]} + \frac{1}{[AOC]} = \frac{2}{ba \sin \beta} + \frac{2}{ca \sin \gamma}
\]
\[
= \left(\frac{2}{a^2 \sin \theta \sin \beta \sin \gamma}\right) (\sin(\theta + \beta) \sin \gamma + \sin(\theta - \gamma) \sin \beta)
\]
\[
= \left(\frac{2}{a^2 \sin \theta \sin \beta \sin \gamma}\right) (\sin \theta \cos \beta \sin \gamma + \cos \theta \sin \beta \sin \gamma + \sin \theta \cos \gamma \sin \beta - \cos \theta \sin \gamma \sin \beta)
\]
\[
= \left(\frac{2}{a^2 \sin \beta \sin \gamma}\right) (\cos \beta \sin \gamma + \cos \gamma \sin \beta) = 2a^{-2} (\cot \beta + \cot \gamma),
\]
which does not depend on the variable quantities \(b, c\) and \(\theta\). The result follows.

592. The incircle of the triangle \(ABC\) is tangent to the sides \(BC, CA\) and \(AB\) at the respective points \(D, E\) and \(F\). Points \(K\) from the line \(DF\) and \(L\) from the line \(EF\) are such that \(AK \parallel BL\parallel DE\). Prove that:

(a) the points \(A, E, F, K\) are concyclic, and the points \(B, D, F, L\) are concyclic;

(b) the points \(C, K, L\) are collinear.

Solution. (a) Since \(AE\) is tangent to the circumcircle of triangle \(DEF\) and since \(AK\parallel BL\),
\[
\angle AEF = \angle EDF = \angle AKF,
\]
whence \(A, E, F, K\) are concyclic. Since \(BC\) is tangent to the circumcircle of triangle \(DEF\) and since \(DE\parallel BL\),
\[
\angle BDF = \angle FED = \angle LED = 180^\circ - \angle BLE = 180^\circ - \angle BLF,
\]
whence \(B, D, F, L\) are concyclic.

(b) Since \(DE\parallel AK\), \(A\) and \(E\) are on the same side of \(DE\) and \(AB\) is tangent to circle \(DEF\), we have that
\[
\angle DEK = \angle EKA = \angle EFA = \angle EDK,
\]
whence \(KD = KE\). Since \(DE\parallel BL\), \(BLFD\) is a concyclic quadrilateral and \(AB\) is tangent to circle \(DEF\), we have that
\[
\angle LDE = \angle BLD = \angle BFD = \angle LED,
\]
whence \(LD = LE\). Since \(CD\) and \(CE\) are tangents to circle \(DEF\), \(CD = CE\). Therefore, all three points \(C, K, L\) lie on the right bisector of \(DE\) and so are collinear.

593. Consider all natural numbers \(M\) with the following properties:

(i) the four rightmost digits of \(M\) are 2008;

(ii) for some natural numbers \(p > 1\) and \(n > 1\), \(M = p^n\).

Determine all numbers \(n\) for which such numbers \(M\) exist.

Solution. Since, modulo 10, squares are congruent to one of \(0, 1, 4, 6, 9\), and \(p^n\) is square for even values of \(n\), there are no even values of \(n\) for which such a number \(M\) exists.

Since \(p^n \equiv 2008 \pmod{10^4}\) implies that \(p^n \equiv 8 \pmod{16}\), we see that \(p\) must be even. When \(p\) is divisible by 4, then \(p^n \equiv 0 \pmod{16}\) for \(n \geq 2\), and when \(p\) is twice an odd number, \(p^n \equiv 0 \pmod{16}\) for \(n \geq 4\). Therefore the only possibility for \(M\) is that it be the cube of a number congruent to 2 \(\pmod{4}\).

The condition that \(p^3 \equiv 2008 \pmod{10^4}\) implies that \(p^3 \equiv 8 \pmod{125}\). Since
\[
p^3 - 8 = (p - 2)(p^2 + 2p + 4) = (p - 2)(p + 1)^2 + 3,
\]

and since the second factor is never divisible by 5 (the squares, modulo 5, are 0, 1, 4), we must have that \( p \equiv 2 \pmod{125} \). Putting this together with \( p \) being twice an odd number, we find that the smallest possibilities are equal to 502 and 1002.

We have that \( 502^3 = 126506008 \) and \( 1002^3 = 1006012008 \). Thus, such numbers \( M \) exist if and only \( n = 3 \).

594. For each natural number \( N \), denote by \( S(N) \) the sum of the digits of \( N \). Are there natural numbers \( N \) which satisfy the condition severally:

(a) \( S(N) + S(N^2) = 2008 \);
(b) \( S(N) + S(N^2) = 2009 \)?

**Solution.** We have that

\[
S(N) + S(N^2) \equiv N + N^2 = N(N + 1) \pmod{9}.
\]

This number is congruent to either 0 or 2, modulo 3. In particular, it can never assume the value of 2008, which is congruent to 1, modulo 3.

For part (b), we try a number \( N \) of the form

\[
N = 1 + 10^3 + 10^6 + \cdots + 10^{9r} ,
\]

where \( 100 \leq r \leq 999 \). Then \( S(N) = r + 1 \),

\[
N^2 = 1 + 2 \cdot 10^3 + 3 \cdot 10^6 + \cdots + r \cdot 10^{9r-1} + (r + 1) \cdot 10^r + r \cdot 10^{9r+1} + \cdots + 2 \cdot 10^{6r-1} + 10^6r
\]

and, since each coefficient of a power of 10 has at most three digits and there is no carry to a digit arising from another power,

\[
S(n^2) = 2 \sum_{k=1}^{r} S(k) + S(r + 1) = 2 \sum_{k=1}^{99} S(k) + 2 \sum_{k=101}^{r} S(k) + S(r + 1).
\]

The numbers less than 100 have 200 digits in all (counting 0 as the first digit of single-digit numbers), each appearing equally often (20 times), so that

\[
2 \sum_{k=1}^{99} S(k) = 2[20(1 + 2 + \cdots + 9)] = 1800 .
\]

Now let \( r = 108 \). Then \( S(100) + S(101) + S(108) = 9 + 36 = 45 \), so that, when \( N = 1001001 \cdots 1001 \) with 109 ones interspersed by double zeros,

\[
\]

Therefore, the equation in (b) is solvable for some natural number \( N \).

595. What are the dimensions of the greatest \( n \times n \) square chessboard for which it is possible to arrange 111 coins on its cells so that the numbers of coins on any two adjacent cells (i.e. that share a side) differ by 1?

**Solution.** We begin by establishing some restrictions. The parity of the number of coins in any two adjacent cells differ, so that at least one of any pair of adjacent cells contains at least one coin. This ensures that the number of cells cannot exceed \( 2 \times 111 + 1 = 2 < 15^2 \), so that \( n \leq 14 \). Since there are 111 cells, there
must be an odd number of cells that contain an odd number of coins. Since in a $14 \times 14$ chessboard, there must be $98 = \frac{1}{2} \times 196$ cells with an odd number of coins, $n = 14$ is not possible.

We show that a $13 \times 13$ chessboard admits a suitable placement of coins. Begin by placing a single coin in every second cell so that each corner cell contains one coin. This uses up 85 coins. Now place two coins in each of thirteen of the remaining 84 vacant cells. We have placed $85 + 26 = 111$ coins in such a ways as to satisfy the condition.

Hence, a $13 \times 13$ chessboard is the largest that admits the desired placement.

596. A $12 \times 12$ square array is composed of unit squares. Three squares are removed from one of its major diagonals. Is it possible to cover completely the remaining part of the array by 47 rectangular tiles of size $1 \times 3$ without overlapping any of them?

Solution. Let the major diagonal in question go from upper left to lower right. Label the cells by letters A, B, C with A in the upper left corner, so that ABC appears in this cyclic order across each row and ACB appears in this cyclic order down each column. There are thus 48 occurrences of each label, and each cell of the major diagonal is labelled with an A. Since each horizontal or vertical placement of $1 \times 3$ tiles must cover one cell with each label, any placement of any number of such tiles must cover equally many cells of each label. However, removing three cells down the major diagonal removes three cells of a single label and leaves of dearth of cells with label A. Therefore, a covering of the remaining 141 cells with 47 tiles is not possible.

597. Find all pairs of natural numbers $(x, y)$ that satisfy the equation
\[
2x(xy - 2y - 3) = (x + y)(3x + y) .
\]

Solution. The given equation can be rewritten as a quadratic in $y$:
\[
y^2 + (8x - 2x^2)y + (3x^2 + 6x) = 0 .
\]
Its discriminant is equal to
\[
(64x^2 - 32x^3 + 4x^4) - 4(3x^2 + 6x) = 4x(x^3 - 8x^2 + 13x - 6) = 4x(x - 6)(x - 1)^2 .
\]
For there to be a solution in integers, it is necessary that this discriminant be a perfect square. This happens if and only of
\[
z^2 = x(x - 6) = (x - 3)^2 - 9 ,
\]
or
\[
9 = (x - 3)^2 - z^2 = (x + z - 3)(x - z - 3) ,
\]
for some integer $z$. Checking all the factorizations $9 = (-9) \times (-1) = (-3) \times (-3) = (1) \times (-9) = 9 \times 1 = 3 \times 3 = 1 \times 9$, we find that $(x, z) = (-2, \pm 4), (0, 0), (8, \pm 4), (6, 0)$.

This leads to a complete solutions set in integers:
\[
(x, y) = (-2, 0), (-2, -8), (-6, 0), (8, 4), (8, 60), (6, 12) .
\]
Therefore, the only solutions in natural numbers to the equation are
\[
(x, y) = (6, 12), (8, 4), (8, 60) ,
\]
all of which check out.
