OLYMON

Produced by the Canadian Mathematical Society and the Department of Mathematics of the University of Toronto.

Issue 10:4

April, 2009

Please send your solutions to

E.J. Barbeau
Department of Mathematics
University of Toronto
40 St. George Street
Toronto, ON M5S 2E4

no later than May 15, 2009. Electronic files can be sent to barbeau@math.utoronto.ca. However, please do not send scanned files; they use a lot of computer space, are often indistinct and can be difficult to download.

It is important that your complete mailing address and your email address appear legibly on the front page. If you do not write your family name last, please underline it.

Problems for April, 2009

612. \(ABCD\) is a rectangle for which \(AB > AD\). A rotation with centre \(A\) takes \(B\) to a point \(B'\) on \(CD\); it takes \(C\) to \(C'\) and \(D\) to \(D'\). Let \(P\) be the point of intersection of the lines \(CD\) and \(C'D'\). Prove that \(CB' = DP\).

613. Let \(ABC\) be a triangle and suppose that

\[
\tan \frac{A}{2} = \frac{p}{u}, \quad \tan \frac{B}{2} = \frac{q}{v}, \quad \tan \frac{C}{2} = \frac{r}{w},
\]

where \(p, q, r, u, v, w\) are positive integers and each fraction is written in lowest terms.

(a) Verify that \(pqv + pvr + uqr = uvw\).

(b) Let \(f\) be the greatest common divisor of the pair \((vw - qr, qw + vr)\), \(g\) be the greatest common divisor of the pair \((uw - pr, pw + ur)\), and \(h\) be the greatest common divisor of the pair \((uv - pq, pv + qu)\). Prove that

\[
fp = vw - qr, \quad fu = qw + vr \\
gq = uv - pr, \quad gv = pw + ur \\
hv = uw - pq, \quad hw = pv + qu.
\]

(c) Prove that the sides of the triangle \(ABC\) are proportional to \(fpu : gqv : hrw\).

614. Determine those values of the parameter \(a\) for which there exist at least one line that is tangent to the graph of the curve \(y = x^3 - ax\) at one point and normal to the graph at another.

615. The function \(f(x)\) is defined for real nonzero \(x\), takes nonzero real values and satisfies the functional equation

\[
f(x) + f(y) = f(xyf(x + y)),
\]

whenever \(xy(x + y) \neq 0\). Determine all possibilities for \(f\).
616. Let $T$ be a triangle in the plane whose vertices are lattice points (i.e., both coordinates are integers), whose edges contain no lattice points in their interiors and whose interior contains exactly one lattice point. Must this lattice point in the interior be the centroid of the $T$?

617. Two circles are externally tangent at $A$ and are internally tangent to a third circle $\Gamma$ at points $B$ and $C$. Suppose that $D$ is the midpoint of the chord of $\Gamma$ that passes through $A$ and is tangent there to the two smaller given circles. Suppose, further, that the centres of the three circles are not collinear. Prove that $A$ is the incentre of triangle $BCD$.

618. Let $a, b, c, m$ be positive integers for which 
\[ abc m = 1 + a^2 + b^2 + c^2. \]
Show that $m = 4$, and that there are actually possibilities with this value of $m$.

**Challenge problems**

The following problems are ones for which I do not have a solution. You are invited to solve them and send in your solution as early as you can. Four of the problems for this month were solved by students, whose solutions I acknowledge with thanks in order of receipt. Now they are for the rest of you to solve.

615. Hunter Spink (28/1/09); Jonathan Schneider (29/1/09)

616. Hunter Spink (28/1/09); Jonathan Schneider (29/1/09)

617. Hunter Spink (28/1/09); Robin Cheng (30/1/09)

618. Jonathan Schneider (29/1/09)

**C5.** Solve the equation
\[ x^{12} - x^9 + x^4 - x = 1. \]

**C6.** [Solved 2/3/09 by Jonathan Schneider] Suppose that $n > 1$ and that $S$ is the set of all polynomials of the form
\[ z^n + a_{n-1}z^{n-1} + a_{n-2}z^{n-2} + \cdots + a_1z + a_0, \]
whose coefficients are complex numbers. Determine the minimum value over all such polynomials of the maximum value of $|p(z)|$ when $|z| = 1$.

**C7.** [Solved 2/3/09 by Jonathan Schneider and 4/3/09 by Cameron Bruggeman] Let $a_1, a_2, \cdots, a_n$ be distinct integers. Prove that the polynomial
\[ p(z) = (z - a_1)^2(z - a_2)^2 \cdots (z - a_n)^2 + 1 \]
cannot be written as the product of two nonconstant polynomials with integer coefficients.

**C8.** [Solved 2/3/09 by Jonathan Schneider] Determine the locus of one focus of an ellipse reflected in a variable tangent to the ellipse.

**C9.** Let $I$ be the centre of the inscribed circle of a triangle $ABC$ and let $u, v, w$ be the respective lengths of $IA, IB, IC$. Let $P$ be any point in the plane and $p, q, r$ the respective lengths of $PA, PB, PC$. Prove that, with the sidelengths of the triangle given conventionally as $a, b, c$,
\[ ap^2 + bq^2 + cr^2 = au^2 + bv^2 + cw^2 + (a + b + c)z^2, \]
where $z$ is the length of $IP$.

**C10.** Given the parameters $a, b, c$, solve the system
\[ x + y + z = a + b + c; \]
\[ x^2 + y^2 + x^2 = a^2 + b^2 + c^2; \]
\[
\frac{x}{a} + \frac{y}{b} + \frac{z}{c} = 3.
\]

C11. Suppose that \(x_i \geq 0\) and
\[
\sum_{i=1}^{n} \frac{1}{1 + x_i} \leq 1.
\]
Prove that
\[
\sum_{i=1}^{n} 2^{-x_i} \leq 1.
\]

C12. Let \(a_i \geq 2,\)
\[
x = \frac{1}{a_1} + \frac{1}{a_1^2a_2} + \frac{1}{a_1^2a_2^2a_3} + \cdots,
\]
\[
x = \frac{1}{a_1} + \frac{1}{a_1^2a_2} + \frac{1}{a_1^2a_2^2a_3} + \cdots.
\]
Prove that either \(x\) and \(y\) are both rational or \(x\) and \(y\) are both irrational.

Solutions

585. Calculate the number
\[
b = \lfloor (\sqrt{n} - 1 + \sqrt{n} + \sqrt{n + 1})^2 \rfloor.
\]

Solution. When \(n = 1\), then \(b = \lfloor 3 + 2\sqrt{3} \rfloor = 5\). When \(n = 2\), then
\[
4.14 = 1 + 1.41 + 1.73 < 1 + \sqrt{2} + \sqrt{3} < 1 + \frac{17}{12} + \frac{7}{4} = \frac{25}{6}
\]
so that \(17 < (1 + \sqrt{2} + \sqrt{3})^2 < 18\) and \(\lfloor (1 + \sqrt{2} + \sqrt{3})^2 \rfloor = 17 = 9 \times 2 - 1\).

Let \(n \geq 3\). Since
\[
\sqrt{n} - 1 + \sqrt{n} = \frac{1}{\sqrt{n} + \sqrt{n + 1} + \sqrt{n}} < \frac{1}{\sqrt{n} + \sqrt{n + 1} - 1} = \sqrt{n} - \sqrt{n - 1},
\]
it follows that \(\sqrt{n - 1} + \sqrt{n + 1} < 2\sqrt{n}\). Also
\[
\sqrt{n - 1} + \sqrt{n} + \sqrt{n + 1} > 3\sqrt{n^3 - n} > \sqrt{9n - 1} ;
\]
the first inequality follows from that of the arithmetic and geometric means, and the second is evident after raising to the sixth power. Therefore \(\sqrt{9n - 1} < \sqrt{n - 1} + \sqrt{n} + \sqrt{n + 1} < 3\sqrt{n}\).

Hence
\[
9n - 1 < (\sqrt{n - 1} + \sqrt{n} + \sqrt{n + 1})^2 < 9n ,
\]
and so \(b = 9n - 1\), when \(n \geq 2\).

598. Let \(a_1, a_2, \ldots, a_n\) be a finite sequence of positive integers. If possible, select two indices \(j, k\) with \(1 \leq j < k \leq n\) for which \(a_j\) does not divide \(a_k\); replace \(a_j\) by the greatest common divisor of \(a_j\) and \(a_k\), and replace \(a_k\) by the least common multiple of \(a_j\) and \(a_k\). Prove that, if the process is repeated, it must eventually stop, and the final sequence does not depend on the choices made.
Determine the number of distinct solutions $x$ with $0 \leq x \leq \pi$ for each of the following equations. Where feasible, give an explicit representation of the solution.

(a) $8 \cos x \cos 2x \cos 4x = 1$;
(b) $8 \cos x \cos 4x \cos 5x = 1$.

Solution 1. (a) It is clear that no multiple of $\pi$ satisfies the equation. So we must have that $\sin x \neq 0$. Multiply the equation by $\sin x$ to obtain

$$8 \sin x \cos x \cos 2x \cos 4x = 4 \sin 2x \cos 2x \cos 4x = 2 \sin 4x \cos 4x = \sin 8x .$$

Hence the given equation is equivalent to $\sin 8x = \sin x$ with $\sin x \neq 0$. Hence, we must have $x + 8x = (2k + 1)\pi$, $8x = (2k)\pi + x$, since $0 \leq x \leq \pi$. These lead to $x = \pi/9$ ($20^\circ$), $x = 2\pi/7$, $x = \pi/3$ ($60^\circ$), $x = 4\pi/7$, $x = 5\pi/9$ ($100^\circ$), $x = 6\pi/7$ ($120^\circ$), $x = 7\pi/9$. Thus there are seven solutions to the equation.

(b) [Z. Liu] It can be checked that no multiple of $\pi$ nor any odd multiple of $\pi/4$ satisfies the equation. The truth of the equation implies that

$$8 \sin x \cos x \cos 5x = 2 \sin 4x \cos 4x \cos 5x = 4 \sin 2x \cos 2x \cos 4x \sin 5x$$

$$= (\sin x \cos 2x)(8 \cos x \cos 4x \cos 5x) = \sin x \cos 2x .$$

Using the product to sum conversion formula yields

$$\sin 13x + \sin 3x = \sin 3x - \sin x ,$$

whence $\sin 13x = \sin(-x)$. Therefore, either $12x = 13x + (-x)$ is an odd multiple of $\pi$ or $14x = 13x + (-x)$ is an even multiple of $\pi$. However, $x = 0, \pi/4, \pi/2, 3\pi/4$ are extraneous solutions that do not satisfy the given equation. Therefore, there are ten solutions, namely

$$x = \frac{\pi}{12}, \frac{5\pi}{12}, \frac{7\pi}{12}, \frac{11\pi}{12}, \frac{\pi}{7}, \frac{3\pi}{7}, \frac{2\pi}{7}, \frac{4\pi}{7}, \frac{5\pi}{7}, \frac{6\pi}{7} .$$

Solution 2. (a) Let $t = \cos x$. Then $\cos 2x = 2t^2 - 1$ and $\cos 4x = 2(2t^2 - 1) - 1 = 8t^4 - 8t^2 + 1$, so that

$$\cos x \cos 2x \cos 4x = t(2t^2 - 1)(8t^4 - 8t^2 + 1) .$$
Let

\[ f(t) = 8t(2t^2 - 1)(8t^4 - 8t^2 + 1) - 1 \]
\[ = 128t^7 - 192t^5 + 80t^3 - 8t - 1 \]
\[ = (2t - 1)(64t^6 + 32t^5 - 80t^4 - 40t^3 + 20t^2 + 10t + 1) \]
\[ = (2t - 1)(8t^3 + 4t^2 - 4t - 1)(8t^3 - 6t - 1) . \]

(The factor \((2t - 1)\) can be found by noting that \(x = \pi/3\), corresponding to \(t = 1/2\), is an obvious solution to the equation given in the problem.)

Let \(g(t) = 8t^3 + 4t^2 - 4t - 1\) and \(h(t) = 8t^3 - 6t - 1\). Since \(g(-1) = -9, h(-1) = -1, g(-\frac{1}{2}) = h(-\frac{1}{2}) = 1, g(0) = h(0) = -1, g(1) = 7\) and \(h(1) = 1\), both of \(g(t)\) and \(h(t)\) have a root in each of the intervals \((-1, -\frac{1}{2}), (-\frac{1}{2}, 0)\) and \((0, 1)\).

Since the only roots of \(g(t) - h(t) = 4t^2 + 2t = 2t(2t + 1)\) are \(\frac{-1}{2}\) and 0, \(g(t)\) and \(h(t)\) do not have a root in common. Therefore, \(f(t)\) has seven roots and these correspond to seven solutions of the given equation.

(b) We have that

\[ 1 = 8 \cos x \cos 4x \cos 5x = 4 \cos^2 4x + 4 \cos 4x \cos 6x \]
\[ = (2 \cos 8x + 2) + (2 \cos 2x + 2 \cos 10x) , \]
so that

\[ 2 \cos 2x + 2 \cos 8x + 2 \cos 10x + 1 = 0 . \]

Substituting \(t = \cos 2x\) yields \(\cos 4x = 2t^2 - 1, \cos 8x = 8t^2 - 4t^2 + 1, \cos 10x = 16t^3 - 20t^3 + 5t\), so that the equation becomes

\[ 0 = (4t^2 - 3)(8t^3 + 4t^2 - 4t - 1) . \]

The polynomial \(4t^2 - 3\) has two roots in the interval \([-1, 1]\) corresponding to four values of \(x\) in the interval \([0, \pi]\). Let \(f(t) = 8t^3 + 4t^2 - 4t - 1\). Since \(f(-1) = -1, f(-\frac{1}{2}) = 1, f(0) = -1, f(1) = 7, f(t)\) has three real roots, once in each of the intervals \((-1, -\frac{1}{2}), (-\frac{1}{2}, 0), (0, 1)\), and each of these corresponds to two solution \(x\) in the interval \([0, \pi]\). Therefore, the equation in \(x\) has ten solutions in the interval.

Comments. (a) The seven solutions of the equation \(\sin 8x = \sin x\) can be seen from a sketch of the graphs of the two functions on the same axes.

(b) Since \(2 \cos x \cos 5x = \cos 4x + \cos 6x\), the equation is equivalent to

\[ 4(\cos^2 4x + \cos 4x \cos 6x) = 1 . \]

Some solutions can be found by solving \(\cos 6x = 0\) and \(\cos^2 4x = \frac{1}{4}\). These are satisfied by \(x = \pi/12, 5\pi/12, 7\pi/12\) and \(11\pi/12\).

The trial, taking \(\cos 4x = \frac{1}{2}\), is also reasonable, as it gives \(x = \pi/12\). With this substitution, the left side become \(4 \cos \pi/12 \sin \pi 12 = 2 \sin \pi/6 = 1\). The other multiples of \(\pi/12\) can be handled in the same way.

When \(t = \cos 2x\), there is another route to the equation in \(t\) to be analyzed. The equation, in the form

\[ 1 = 4(\cos 4x)(\cos 4x + \cos 6x), \]

is transformed to

\[ 1 = 4(2t^2 - 1)(2t^2 - 1 + 4t^3 - 3t) = 4(8t^5 + 4t^4 - 10t^2 - 4t^2 + 3t + 1) . \]

This simplifies to

\[ 0 = 32t^5 + 16t^4 - 40t^3 - 16t^2 + 12t + 3 \]
\[ = (4t^2 - 3)(8t^3 + 4t^2 - 4t - 1) . \]

Since \(x = \pi/12\) is a solution, \(t = \cos \pi/6 = \sqrt{3}/2\) satisfies the equation in \(t\) and accounts for the factor \(4t^2 - 3\) on the right side of the equation.
600. Let \( 0 < a < b \). Prove that, for any positive integer \( n \),

\[
\frac{b + a}{2} \leq \sqrt[2]{\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)}} \leq \sqrt[2]{\frac{a^n + b^n}{2}}.
\]

**Solution 1.** Dividing the inequality through by \((b + a)/2\) yields the equivalent inequality

\[
1 \leq \sqrt[2]{\frac{b^{n+1} - a^{n+1}}{(b - a')(n + 1)}} \leq \sqrt[2]{\frac{a^n + b^n}{2}}
\]

with \( a' = (2a)/(b + a) \) and \( b' = (2b)/(b + a) \). Note that \((a' + b')/2 = 1\), and we can write \( b' = 1 + u \) and \( a' = 1 - u \) with \( 0 < u < 1 \). The central term becomes the \( n \)th root of

\[
\frac{(1 + u)^{n+1} - (1 - u)^{n+1}}{2(n + 1)u} = 2[(n + 1)u + \left(\frac{n+1}{3}\right)u^3 + \left(\frac{n+1}{5}\right)u^5 + \cdots]
\]

\[
= 1 + \frac{1}{3} \binom{n}{2} u^2 + \frac{1}{5} \binom{n}{4} u^4 + \cdots
\]

which clearly exceeds 1 and gives the left inequality. The right term become the \( n \)th roots of

\[
\frac{1}{2}[(1 + u)^n + (1 - u)^n] = 1 + \binom{n}{2} u^2 + \binom{n}{4} u^4 + \cdots
\]

and the right inequality is true.

**Solution 2.** The inequality

\[
\sqrt[2]{\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)}} \leq \sqrt[2]{\frac{a^n + b^n}{2}}
\]

is equivalent to

\[
0 \leq (n + 1)(a^n + b^n) - \frac{2(b^{n+1} - a^{n+1})}{b - a}.
\]

The right side is equal to

\[
(n + 1)(a^n + b^n) - 2(b^n + b^{n-1}a + b^{n-2}a^2 + \cdots + b^2a^{n-2} + ba^{n-1} + a^n)
\]

\[
= (a^n - b^n) + (a^n - b^{n-1}a) + (a^n - b^{n-2}a) + \cdots + (a^n - ba^{n-1}) + (a^n - a^n)
\]

\[
+ (b^n - b^n) + (b^n - b^{n-1}a) + \cdots + (b^n - ba^{n-1}) + (b^n - a^n)
\]

\[
= (a^n - b^n) + a(a^{n-1} - b^{n-1}) + \alpha^2(a^{n-2} - b^{n-2}) + \cdots + a^{n-1}(a - b) + 0
\]

\[
+ 0 + b^{n-1}(b - a) + \cdots + b(b^{n-1} - a^{n-1}) + (b^n - a^n)
\]

\[
= 0 + (b - a)(b^{n-1} - a^{n-1}) + (b^2 - a^2)(b^{n-2} - a^{n-2}) + \cdots + (b^{n-1} - a^{n-1})(b - a)
\]

\[
> 0.
\]

The left inequality

\[
\frac{b + a}{2} \leq \sqrt[2]{\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)}}
\]

is equivalent to

\[
\left(\frac{b + a}{2}\right)^n \leq \frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)}.
\]
Let \( v = \frac{1}{2}(b - a) \) so that \( b + a = 2(a + v) \). Then

\[
\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)} - \left( \frac{b + a}{2} \right)^n = \frac{(a + 2v)^{n+1} - a^{n+1}}{(b - a)(n + 1)} - (a + v)^n
\]

\[
= \frac{1}{2v(n + 1)} \left( \sum_{k=0}^{n+1} \binom{n+1}{k} a^{n+1-k} (2v)^k \right) - (a + v)^n
\]

\[
= \frac{1}{n + 1} \left( \sum_{k=0}^{n+1} \binom{n+1}{k} a^{n-(k-1)} (2v)^k \right) - (a + v)^n
\]

\[
= \frac{1}{n + 1} \left( \sum_{k=0}^{n+1} \binom{n+1}{k} a^{n-k} (2v)^k \right) - \frac{n}{k} a^{n-k} v^k
\]

\[
= \left( \sum_{k=0}^{n} \frac{1}{k+1} \binom{n}{k} a^{n-k} (2v)^k \right) - \frac{n}{k} a^{n-k} v^k
\]

\[
= \sum_{k=0}^{n} \left( \frac{2^k}{k+1} - 1 \right) \binom{n}{k} a^{n-k} v^k \geq 0 ,
\]

since \( 2^k = (1 + 1)^k = 1 + k + \binom{k}{2} + \cdots + 1 + k \) with equality if and only if \( k = 0 \) or \( 1 \). The result follows.

**Solution 3.** [D. Nicholson] (partial) Let \( n \geq 2i + 1 \). Then

\[
(b^{n-i}a^i + b'a^{n-i}) - (b^{n-i-1}a^{i+1} + b^{i+1}a^{n-i-1}) = (b - a)a^ib'^i(b^{n-2i-1} - a^{n-2i-1}) \geq 0 .
\]

Hence, for \( 0 \leq j \leq \frac{1}{2}(n+1) \),

\[
b^n + a^n \geq b^{n-1}a + ab^{n-1} \geq \cdots \geq b^{n-j}a^j + b^j a^{n-j} .
\]

When \( n = 2k + 1 \),

\[
b^n + b^{n-1}a + \cdots + ba^{n-1} + a^n = \sum_{i=0}^{k} (b^{n-i}a^i + b^ia^{n-i}) \leq (k + 1)(b^n + a^n) = \frac{n + 1}{2} (b^n + a^n)
\]

and when \( n = 2k \), we use the Arithmetic-Geometric Means Inequality to obtain \( b^k a^k \leq \frac{1}{2}(b^{2k} + b^{2k}) \), so that

\[
b^n + b^{n-1}a + \cdots + ba^{n-1} + a^n = \sum_{i=0}^{k-1} (b^{n-i}a^i + b^ia^{n-i}) + b^k a^k \leq k(b^n + a^n) + \frac{b^n + a^n}{2} = \frac{n + 1}{2} (b^n + a^n) .
\]

Hence

\[
\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)} \leq \frac{b^n + a^n}{2} .
\]

**Solution 4.** [Y. Shen] Let \( 1 \leq k \leq n \) and \( 1 \leq i \leq k \). Then

\[
(b^{k+1} + a^{k+1}) - (b^ia^{k+1-i} + a^ib^{k+1-i}) = (b^i - a^i)(b^{k+1-i} - a^{k+1-i}) \geq 0 .
\]

Hence

\[
k(b^{k+1} + a^{k+1}) \geq \sum_{i=1}^{k} (b^ia^{k+1-i} + a^ib^{k+1-i}) = 2 \sum_{i=1}^{k} b^ia^{k+1-i} .
\]
This is equivalent to

\[
(2k + 2) \sum_{i=0}^{k+1} b^i a^{k+1-i} = (2k + 2)(b^{k+1} + a^{k+1}) + (2k + 2) \sum_{i=1}^{k} b^i a^{k+1-i}
\]

\[
\geq (k + 2)(b^{k+1} + a^{k+1}) + (2k + 4) \sum_{i=1}^{k} b^i a^{k+1-i}
\]

\[
= (k + 2)(b^{k+1} + 2k a^{k+1-i} + a^{k+1})
\]

\[
= (k + 2)(b + a) \sum_{i=0}^{k} b^i a^{k-i}
\]

which in turn is equivalent to

\[
\frac{\sum_{i=0}^{k+1} b^i a^{k+1-i}}{k + 2} \geq \frac{(b + a)(\sum_{i=0}^{k} b^i a^{k-i})}{2(k + 1)}
\]

We establish by induction that

\[
\left(\frac{b + a}{2}\right)^n \leq \frac{1}{n + 1} \sum_{i=0}^{n} b^i a^{n-i}
\]

which will yield the left inequality. This holds for \( n = 1 \). Suppose that it holds for \( n = k \). Then

\[
\left(\frac{b + a}{2}\right)^k = \left(\frac{b + a}{2}\right) \cdot \left(\frac{b + a}{2}\right)^k
\]

\[
\leq \left(\frac{b + a}{2}\right) \cdot \left(\frac{1}{k + 1}\right) \sum_{i=0}^{k} b^i a^{k-i} \leq \frac{1}{k + 2} \sum_{i=0}^{k+1} b^i a^{k-i}
\]

As above, we have, for \( k = n - 1 \),

\[
(n - 1)(b^n + a^n) \geq 2 \sum_{i=1}^{n-1} b^i a^{n-i}
\]

so that

\[
(n + 1)(b^n + a^n) \geq 2 \sum_{i=0}^{n} b^i a^{n-i} = 2 \left(\frac{b^{n+1} - a^{n+1}}{b - a}\right)
\]

from which the right inequality follows.

**Comment.** The inequality

\[
\frac{b + a}{2} \leq \sqrt{\frac{b^{n+1} - a^{n+1}}{(b - a)(n + 1)}}
\]

is equivalent to

\[
0 \leq \frac{2^n (b^{n+1} - a^{n+1})}{b - a} - (n + 1)(b + a)^n.
\]

When \( n = 1 \), the right side is equal to 0. When \( n = 2 \), it is equal to

\[
4(b^2 + ba + a^2) - 3(b + a)^2 = (b - a)^2 > 0.
\]

8
When $n = 3$, we have
\[ 8(b^3 + b^2a + ba^2 + a^3) - 4(b + a)^3 = 4b^3 - 4b^2a - 4ba^2 + 4a^3 = 4(b^2 - a^2)(b - a) = 4(b + a)(b - a)^2 > 0. \]

When $n = 4, 5$ and $6$, the right side is, respectively,
\[ (11b^2 + 18ab + 11a^2)(b - a)^2 \]
\[ (26b^3 + 54b^2a + 54ba^2 + 26a^3)(b - a)^2 \]
\[ (57b^4 + 136b^3a + 174b^2a^2 + 136ba^3 + 57a^4)(b - a)^2. \]

There is a pattern here; can anyone express it in a general way that will yield the result, or at least show that the right side is the product of $(b - a)^2$ and a polynomial with positive coefficients?

601. A convex figure lies inside a given circle. The figure is seen from every point of the circumference of the circle at right angles (that is, the two rays drawn from the point and supporting the convex figure are perpendicular). Prove that the centre of the circle is a centre of symmetry of the figure.

**Solution 1.** Let the figure be denoted by $\mathfrak{F}$ and the circle by $\mathfrak{C}$, and let $\rho$ be the central reflection through the centre of the circle. Suppose that $m$ is any line of support for $\mathfrak{F}$ and that it intersects the circle in $P$ and $Q$. Then there are lines $p$ and $q$ through $P$ and $Q$ respectively, perpendicular to $m$, which support $\mathfrak{F}$. Let $p$ meet the circle in $P$ and $R$, and $q$ meet it in $Q$ and $S$; let $t$ be the line $RS$. Since $PQRS$ is concyclic with adjacent right angles, it is a rectangle, and $t$ is a line of support of $\mathfrak{F}$. Since $PS$ and $RQ$ are both diameters of $\mathfrak{C}$, it follows that $S = \rho(P), R = \rho(Q)$ and $t = \rho(m)$.

Hence, every line of support of $\mathfrak{F}$ is carried by $\rho$ into a line of support of $\mathfrak{F}$. We note that $\mathfrak{F}$ must be on the same side of its line of support as the centre of the circle.

Suppose that $X \in \mathfrak{F}$. Let $Y = \rho(X)$. Suppose, if possible that $Y \notin \mathfrak{F}$. Then there must be a disc containing $Y$ that does not intersect $\mathfrak{F}$, so we can find a line $m$ of support for $\mathfrak{F}$ such that $\mathfrak{F}$ is on one side and $Y$ is strictly on the other side of $m$. Let $n = \rho(m)$. Then $n$ is a line of support for $\mathfrak{F}$ which has $X = \rho(Y)$ on one side and $O = \rho(O)$ on the other. But this is not possible. Hence $Y \in \mathfrak{F}$ and so $\rho(\mathfrak{F}) \subseteq \mathfrak{F}$. Now $\rho\circ\rho$ is the identity mapping, so $\mathfrak{F} = \rho(\rho(\mathfrak{F})) \subseteq \rho(\mathfrak{F})$. It follows that $\mathfrak{F} = \rho(\mathfrak{F})$ and the result follows.

**Solution 2.** Let $P$ be any point on the circle $\mathfrak{C}$. There are two perpendicular lines of support from $P$ meeting the circle in $Q$ and $S$. As in the first solution, we see that $P$ is one vertex of a rectangle $PQRS$ each of whose sides supports $\mathfrak{F}$. Let $\mathfrak{S}$ be the intersection of all the rectangles as $P$ ranges over the circumference of the circle $\mathfrak{C}$. Since each rectangle has central symmetry about the centre of $\mathfrak{C}$, the same is true of $\mathfrak{S}$. It is clear that $\mathfrak{F} \subseteq \mathfrak{S}$. It remains to show that $\mathfrak{S} \subseteq \mathfrak{F}$. Suppose a point $X$ in $\mathfrak{S}$ does not belong to $\mathfrak{F}$. Then there is a line $r$ of support to $\mathfrak{F}$ for which $X$ and $\mathfrak{F}$ are on opposite sides. This line of support intersects $\mathfrak{C}$ at the endpoints of a chord which must be a side of a supporting rectangle for $\mathfrak{F}$. The point $X$ lies outside this rectangle, and so must lie outside of $\mathfrak{S}$. The result follows.

**Solution 3.** [D. Arthur] If the result is false, then there is a line through the centre of the circle such that $OP > OQ$, where $P$ is where the line meets the boundary of the figure on one side and $Q$ is where it meets the boundary on the other. Let $m$ be the line of support of the figure through $Q$. Then, as shown in Solution 1, its reflection $t$ in the centre of the circle is also a line of support. But then $P$ and $O$ lie on opposite sides of $t$ and we obtain a contradiction.

602. Prove that, for each pair $(m, n)$ of integers with $1 \leq m \leq n$,
\[
\sum_{i=1}^{n} i(i-1)(i-2) \cdots (i-m+1) = \frac{(n+1)n(n-1) \cdots (n-m+1)}{m+1}.
\]
(b) Suppose that \(1 \leq r \leq n\); consider all subsets with \(r\) elements of the set \(\{1, 2, \ldots, n\}\). The elements of this subset are arranged in ascending order of magnitude. For \(1 \leq i \leq r\), let \(t_i\) denote the \(i\)th smallest element in the subset, and let \(T(n, r, i)\) denote the arithmetic mean of the elements \(t_i\). Prove that

\[ T(n, r, i) = i \left( \frac{n + 1}{r + 1} \right). \]

(a) Solution 1. \(i(i - 1)(i - 2) \cdots (i - m + 1) = \frac{[i(i+1)-m]}{m+1} i(i-2) \cdots (i-m+1) \)

\[= \frac{(i+1)i(i-1) \cdots (i-m+1) - i(i-1)(i-2) \cdots (i-m+1)(i-m)}{m+1} \]

so that

\[\sum_{i=1}^{n} i(i-1)(i-2) \cdots (i-m+1) = \sum_{i=2}^{n+1} \frac{i(i-1) \cdots (i-m)}{m+1} - \sum_{i=1}^{n} \frac{i(i-1) \cdots (i-m)}{m+1} \]

\[= \frac{(n+1)n(n-1) \cdots (n-m+1)}{m+1} - 0 \]

\[= \frac{(n+1)n(n-1) \cdots (n-m+1)}{m+1}. \]

(a) Solution 2. [W. Choi] Recall the identity

\[\sum_{i=m}^{n} \left( \frac{i}{m} \right) = \left( \frac{n+1}{m+1} \right)\]

which is obvious for \(n = m\) and can be established by induction for \(n \geq m+1\). There is an alternative combinatorial argument. Consider the number \(\binom{n+1}{m+1}\) of selecting \(m+1\) numbers from the set \(\{1, 2, 3, \ldots, n\}\). The largest number must be \(i+1\) where \(m \leq i \leq n\), and the number of \((m+1)\) sets for which the largest number is \(i+1\) is \(\binom{n}{m}\). Summing over all relevant \(i\) yields the result.

We have that

\[\sum_{i=1}^{m} i(i-1) \cdots (i-m+1) = \sum_{i=m}^{n} \frac{i!}{(i-m)!} = m! \sum_{i=m}^{n} \binom{i}{m} = m! \binom{n+1}{m+1}\]

\[= \frac{(n+1)!}{(m+1)(n-m)!} = \frac{(n+1)n(n-1) \cdots (n-m+1)}{m+1} . \]

(a) Solution 3. [K. Yeats] Let \(n = m + k\). Then

\[\sum_{i=1}^{n} i(i-1)(i-2) \cdots (i-m+1) = m! + \frac{(m+1)!}{1!} + \cdots + \frac{n!}{(n-m)!}\]

\[= \frac{1}{(m+1)!k!} \left[ (m+1)!k! + \frac{(m+1)k!(m+1)}{1!} + \frac{(m+2)k!(m+1)}{2!} + \cdots + n!(m+1) \right]\]

\[= \frac{(m+1)!}{(m+1)!k!} \left[ k! + \frac{k!}{1!}(m+1) + \frac{k!}{2!}(m+2)(m+1) + \cdots + n(n-1) \cdots (m+2)(m+1) \right]. \]

The quantity in square brackets has the form (with \(q = 0\))

\[\frac{k!}{q!} + \frac{k!}{(q+1)!}(m+1) + \frac{k!}{(q+2)!}(m+q+2)(m+1) + \frac{k!}{(q+3)!}(m+q+3)(m+q+2)(m+1) + \cdots\]
Replacing

Hence

number of ordered

Also,

over

as desired. When

This is clear for

(A variant, due to D. Nicholson, uses an induction on

\[ \sum_{i=m}^{r} i(i-1)\cdots(i-m+1) = \frac{(r+1)!}{(r-m)!(m+1)} \]

(a) Solution 4. For 1 ≤ i ≤ m−1, i(i−1)\cdots(i−m+1) = 0. For m ≤ i ≤ n, i(i−1)\cdots(i−m+1) = m!\(_{i}^{n}\).

Also,

\[ \frac{(n+1)n\cdots(n-m+1)}{m+1} = m!\(_{m+1}^{n+1}\) \]

so the statement is equivalent to

\[ \sum_{m}^{n} \(_{m}^{i}\) = \(_{m+1}^{n+1}\) \]

This is clear for n = m. Suppose it holds for n = k ≥ m. Then

\[ \sum_{i=m}^{k+1} \(_{m}^{i}\) = \(_{m+1}^{k+1}\) + \(_{m}^{k+1}\) = \(_{m+1}^{k+2}\) \]

and the result follows by induction.

(a) Solution 5. Use induction on n. If n = 1, then m = 1 and both sides of the equation are equal to 1. Suppose that the result holds for n = k and 1 ≤ m ≤ k. Then, for 1 ≤ m ≤ k,

\[ \sum_{i=1}^{k+1} i(i-1)\cdots(i-m+1) = \frac{(k+1)k(k-1)\cdots(k-m+1)}{m+1} + \frac{(k+1)k(k-1)\cdots(k-m+2)}{m+1} \]

\[ = \frac{(k+1)k(k-1)\cdots(k-m+2)}{m+1} \[ (k-m+1) + (m+1) \]

\[ = \frac{(k+2)(k+1)(k-1)\cdots(k-m+2)}{m+1} \]

as desired. When m = n = k + 1, all terms on the left have k + 1 terms and so they vanish except for the one corresponding to i = k + 1. This one is equal to (k + 1)! and so to the right side.

(b) Solution 1. For 1 ≤ i ≤ r ≤ n, let S(n, r, i) be the sum of the elements t_1 where (t_1, t_2, \cdots, t_r) runs over r-tuples with 1 ≤ t_1 < t_2 < \cdots < t_r ≤ n. Then S(n, r, i) = \(_{i}^{n}\)T(n, r, i). For 1 ≤ k ≤ n, 1 ≤ i ≤ r, the number of ordered r-tuples (t_1, t_2, \cdots, t_r) with t_i = k is \(_{i-1}^{k-1}\(_{r-k}^{n-k}\)) where \(_{0}^{0}\) = 1 and \(_{0}^{k}\) = 0 when b > a. Hence

\[ \(_{n}^{r}\) = \sum_{k=1}^{n} \(_{k-1}^{k-1}\(_{r-k}^{n-k}\) \]

Replacing n by n + 1 and r by r + 1 yields a reading

\[ \(_{n+1}^{r+1}\) = \sum_{k=1}^{n+1} \(_{k-1}^{k-1}\(_{r-k}^{n+1-k}\) \]

for 1 ≤ i ≤ r + 1.
Thus so When 1 ≤ \( i \) ≤ \( r \), the first term of the sum is 0, so that
\[
\binom{n+1}{r+1} = \sum_{k=2}^{n+1} \binom{k-1}{i-1} \binom{n+1-k}{r-i} = \sum_{k=1}^{n} \binom{k}{i} \binom{n-k}{r-i}.
\]

Thus
\[
S(n, r, i) = \sum_{k=1}^{n} \binom{k}{i} \binom{n-k}{r-i} = i \sum_{k=1}^{n} \binom{k}{i} \binom{n-k}{r-i} = i \binom{n+1}{r+1}.
\]

So
\[
T(n, r, i) = i \binom{n+1}{r+1}.
\]

(b) **Solution 2.** [Z. Liu] Define \( S(n, r, i) \) for 1 ≤ \( i \) ≤ \( r \) ≤ \( n \) as in Solution 1. We prove by induction that
\[
S(n, r, i) = i \binom{n+1}{r+1}
\]
from which
\[
T(n, r, i) = i \binom{n+1}{r+1}.
\]

For each positive integer \( n \), we have that \( S(n, 1, 1) = 1 + 2 + \cdots + n = \binom{n+1}{2} \) and \( S(n, n, i) = i \). Suppose that \( n \geq 2, r \geq 2 \) and that \( S(k, r, 1) = \binom{k+1}{r+1} \) for 1 ≤ \( k \) ≤ \( n-1 \). Of the \( \binom{n}{r} \) \( r \)-tuples from \( \{1, 2, \cdots, n\} \), \( \binom{n-1}{r-1} \) of them have smallest element equal to 1, and \( \binom{n-1}{r-1} \) of them have smallest element exceeding 1. The latter set of \( r \)-tuples can be put into one-one correspondence with \( r \)-tuples of \( \{1, 2, \cdots, n-1\} \) by subtracting one from each entry. Therefore the sum of the first (smallest) elements of the latter \( r \)-tuples is \( \binom{n-1}{r} + S(n-1, r, 1) \). Hence
\[
S(n, r, 1) = \binom{n-1}{r-1} + \binom{n-1}{r} + S(n-1, r, 1) = \binom{n}{r} + \binom{n}{r+1} = \binom{n+1}{r+1}.
\]

Suppose as an induction hypothesis that
\[
S(m, s, j) = j \binom{m+1}{s+1}
\]
for 1 ≤ \( j \) ≤ \( s \) ≤ \( n-1 \). This holds for \( n = 2 \). Let \( r \geq 2 \) and 1 ≤ \( i \) ≤ \( r \) ≤ \( n-1 \). Consider the ordered \( r \)-subsets of \( \{1, 2, \cdots, n\} \). There are \( \binom{n-1}{r-1} \) of them that begin with 1; making use of the one-one correspondence between these and \( (r-1) \)-subsets of \( \{1, 2, \cdots, n-1\} \) obtained by subtracting 1 from each entry beyond the first, we have that the sum of the \( i \)th elements of these is
\[
\binom{n-1}{r-1} + S(n-1, r-1, i-1) = \binom{n-1}{r-1} + (i-1) \binom{n}{r}.
\]

There are \( \binom{n-1}{r} \) of the ordered subsets that do not begin with 1; making use of the one-one correspondence between these subsets and the \( r \)-subsets of \( \{1, 2, \cdots, n-1\} \) obtained by subtracting 1 from each entry, we find that the sum of the \( i \)th elements is
\[
\binom{n-1}{r} + S(n-1, r, i) = \binom{n-1}{r} + i \binom{n}{r+1}.
\]
Hence the sum of the $i$th elements of all these $r$−subsets is

$$S(n, r, i) = \left[ \binom{n-1}{r-1} + \binom{n-1}{r} - \binom{n}{r} \right] + i \left[ \binom{n}{r} + \binom{n}{r+1} \right] = 0 + i \binom{n+1}{r+1}.$$ 

Putting all these elements together yields the result.

(b) **Solution 3.** When $r = 1$, we have that

$$T(n, 1, 1) = \frac{1 + 2 + \cdots + n}{n} = \frac{n + 1}{2}.$$ 

When $r = 2$, the subsets are \{1, 2\}, \{1, 3\}, · · · , \{1, n\}, \{2, 3\}, \{2, 4\}, · · · , \{2, n\}, · · · , \{n − 1, n\}, so that

$$T(n, 2, 1) = \frac{1 \times (n − 1) + 2 \times (n − 2) + \cdots + (n − 1) \times 1}{n(n − 1)/2}$$

$$= \frac{\sum_{j=1}^{n-1} [1 + 2 + \cdots + (n − j)]}{n(n − 1)/2} = \frac{\sum_{j=1}^{n-1} (n − j + 1)(n − j)/2}{n(n − 1)/2}$$

$$= \frac{(1/6)(n + 1)n(n − 1)}{(1/2)n(n − 1)} = \frac{n + 1}{3},$$

and

$$T(n, 2, 2) = \frac{(n − 1) \times n + (n − 2) \times (n − 1) + \cdots + 1 \times 2}{n(n − 1)/2} = \frac{(n + 1)n(n − 1)/3}{n(n − 1)/2} = 2 \binom{n + 1}{3}.$$ 

Thus, the result holds for $n = 1, 2$ and all $i, r$ with $1 ≤ i ≤ r ≤ n$, and for all $n$ and $1 ≤ i ≤ r ≤ 2$. Suppose as an induction hypothesis, we have established the result up to $n − 1$ and all appropriate $r$ and $i$, and for $n$ and $1 ≤ i ≤ r − 1$. The $r$−element subsets of \{1, 2, · · · , $n$\} have $\binom{n−1}{r−1}$ instances without $n$ and $\binom{n−1}{r−1}$ instances with $n$.

Let $1 ≤ i ≤ r − 1$. Then

$$T(n, r, i) = \frac{\binom{n−1}{r−1}T(n−1, r−1, i) + \binom{n−1}{r−1}T(n−1, r−1, i)}{\binom{n}{r−1}}$$

$$= \frac{i[\binom{n−1}{r−1} \cdot \binom{n−1}{r−1} \cdot \binom{n}{r−1}]}{\binom{n}{r−1}} = \frac{i[\binom{n}{r−1} + \binom{n}{r−1}]}{\binom{n}{r−1}}$$

$$= i \binom{n+1}{r−1} = i \binom{n+1}{r+1}.$$ 

Also

$$T(n, r, r) = \frac{\binom{n−1}{r−1}T(n−1, r−1) + \binom{n−1}{r−1}n}{\binom{n}{r−1}}$$

$$= \frac{\binom{n−1}{r−1} \cdot \binom{n−1}{r−1} \cdot \binom{n}{r−1} + \binom{n−1}{r−1} \cdot \binom{n}{r−1} \cdot \binom{n}{r−1}}{\binom{n}{r−1}} = r \binom{n}{r−1} + \binom{n}{r−1} = r \binom{n+1}{r+1}.$$ 

(b) **Solution 4.** For $1 ≤ i ≤ r ≤ n$, let $S(n, r, i)$ be the sum of the elements $t_i$ where $(t_1, t_2, · · · , t_r)$ runs over $r$-tuples with $1 ≤ t_1 < t_2 < · · · < t_r ≤ n$. Then $S(n, r, i) = \binom{n}{r}T(n, r, i)$. We observe first that

$$S(n, r, i) = S(n−1, r−1, i) + S(n−2, r−1, i) + · · · + S(r−1, r−1, i)$$

13
for \(1 \leq i \leq r - 1\). This is true, since, for each \(j\) with \(1 \leq j \leq n - r + 1\), \(S(n - j, r - 1, i)\) adds the \(t_i\) over all \(r\)-tuples for which \(t_r = n - j + 1\).

Now \(S(n, 1, 1) = 1 + 2 + \cdots + n = \frac{1}{2}n(n + 1)\) and \(S(n, 2, 1) = \frac{1}{2}n(n - 1) + \cdots + 1 = \frac{1}{24}n(n + 1)n(n - 1)\). As an induction hypothesis, suppose that \(S(n, r - 1, 1) = \frac{1}{r!}(n + 1)n(n - 1) \cdots (n - r + 2)\). Then

\[
S(n, r, 1) = \sum_{k=r-1}^{n-1} S(k, r, 1, 1)
\]

\[
= \frac{1}{r!} \sum_{k=r-1}^{n-1} (k + 1)(k - 1)\cdots(k - r + 2)
= \frac{1}{r!} \sum_{k=1}^{n} k(k - 1)\cdots(k - r + 1)
\]

\[
= \frac{1}{(r + 1)!} (n + 1)n(n - 1)\cdots(n - r + 1) = \left(\frac{n + 1}{r + 1}\right) \binom{n}{r}.
\]

Thus, for each \(r\) with \(1 \leq r \leq n\), \(S(n, r, 1) = \binom{n}{r}(n + 1)/(r + 1)\) so that \(T(n, r, 1) = (n + 1)/(r + 1)\).

Let \(n \geq 2\). Suppose that for \(1 \leq k \leq n - 1\) and \(1 \leq i \leq r \leq k\), it has been established that \(S(k, r, i) = iS(k, r, 1)\). Then for \(1 \leq i \leq r \leq n\),

\[
S(n, r, i) = S(n - 1, r - 1, i) + S(n - 2, r - 1, i) + \cdots + S(r - 1, r - 1, i) = iS(n - 1, r - 1, 1) + S(n - 2, r - 1, 1) + \cdots + S(r - 1, r - 1, 1) = iS(n, r, 1).
\]

Dividing by \(\binom{n}{r}\) yields

\[
T(n, r, i) = iT(n, r, 1) = i\left(\frac{n + 1}{r + 1}\right).
\]

Comments. (1) There is a one-one correspondence

\[
(t_1, t_2, \ldots, t_r) \leftrightarrow (n + 1 - t_r, n + 1 - t_{r-1}, \ldots, n + 1 - t_1)
\]

of the set of suitable \(r\)-tuples to itself, it follows that

\[
S(n, r, r) = \left(\frac{n}{r}\right)(n + 1) - S(n, r, 1) = \left(\frac{n}{r}\right)(1 + 1)\left(1 - \frac{1}{r + 1}\right)
\]

\[
= \frac{r(n + 1)}{r + 1} \binom{n}{r} = rS(n, r, 1)
\]

from which \(T(n, r, r) = r(n + 1)/(r + 1) = rT(n, r, 1)\).

(2) To illustrate another method for getting and using the recursion, we prove first that \(T(n, r, 2) = 2T(n, r, 1)\) for \(2 \leq r \leq n\). Consider the case \(r = 2\). For \(1 \leq t_1 < t_2 \leq n\), \((t_1, t_2) \leftrightarrow (t_2 - t_1, t_2)\) defines a one-one correspondence between suitable pairs. Since \(t_2 = t_1 + (t_2 - t_1)\), it follows from this correspondence that \(S(n, 2, 2) = 2S(n, 2, 1)\). Dividing by \(\binom{n}{2}\) yields \(T(n, 2, 2) = 2T(n, 2, 1)\).

Suppose that \(r \geq 2\). For each positive integer \(j\) with \(1 \leq j \leq n - r + 1\), we define a one-one correspondence between \(r\)-tuples \((t_1, t_2, \ldots, t_r)\) with \(1 \leq t_1 < t_2 < \cdots < t_r \leq n\) and \(S_3 - t_2 = j\) and \((r - 1)\)-tuples \((s_1, s_2, s_3, \ldots, s_r)\) with \(1 \leq s_1 < s_2 < s_3 = t_3 - j < \cdots < s_r = t_r - j \leq n - j\). The sum of the elements \(t_2\) over all \(r\)-tuples with \(t_3 - t_2 = j\) is equal to the sum of \(t_2\) over all the \((r - 1)\)-tuples. Hence

\[
S(n, r, 2) = S(n, r - 1, 2) + S(n - 2, r - 1, 2) + \cdots + S(r - 1, r - 1, 2).
\]
More generally, for \(1 \leq j \leq n - r - 1\), there is a one-one correspondence between \(r\)-tuples \((t_1, t_2, \cdots, t_r)\) with \(t_{i+1} - t_i = j\) and \((r-1)\)-tuples \((s_1, s_2, \cdots, s_{r-1}) = (t_1, \cdots, t_i, t_{i+2} - j, \cdots, t_r - j)\) with \(1 \leq s_1 = t_1 < \cdots < s_i = t_i < s_{i+1} = t_{i+2} - j < \cdots < s_{r-1} = t_r - j \leq n - j\). We now use induction on \(r\). We have that
\[
S(n, r, i) = S(n-1, r-1, i) + S(n-2, r-1, i) + \cdots + S(r-1, r-1, i) .
\]

(b) Solution 5. [Y. Shen] We establish that
\[
\sum_{k=i}^{i+(n-r)} \binom{k}{i} \binom{n-k}{r-i} = \binom{n+1}{r+1} .
\]

Consider the \((r+1)\)-element sets where \(t_{i+1} = k + 1\) and \(t_{r+1} \leq n + 1\). We must have \(i \leq k \leq n - (r - i)\) and there are \(\binom{k}{i} \binom{n-k}{r-i}\) ways of selecting \(t_1, \cdots, t_i\) and \(t_{i+2}, \cdots, t_{r+1}\). The desired equation follows from a counting argument over all possibilities for \(t_{i+1}\).

In a similar way, we note that \(t_i = k\) for \(\binom{k-1}{i-1} \binom{n-k}{r-i}\) sets \(\{t_1, \cdots, t_r\}\) chosen from \(\{1, \cdots, n\}\), where \(1 \leq k \leq n - r + 1\). Observe that
\[
\binom{k-1}{i-1} \binom{n-k}{r-i} = \frac{(k-1)!}{(i-1)!(n-k-i+1)!} \frac{(n-k)!}{(r-i)!(n-k-r+i)!} = \frac{(n-k)!}{(r-i)!(i-1)!(n-k-i+1)!(n-k-r+i)!} .
\]

Then
\[
T(n, r, i) \equiv \sum_{k=i}^{i+(n-r)} \binom{k}{i} \binom{n-k}{r-i} = \binom{n+1}{r+1} .
\]

(b) Solution 6. [Christopher So] Note that
\[
\sum_{k=i}^{i+(n-r)} \binom{k}{i} \binom{n-k}{r-i}
\]
is the coefficient of \(x^i y^{r-i}\) in the polynomial
\[
\sum_{k=i}^{i+(n-r)} \frac{(1 + x)^k (1 + y)^{n-k}}{(r-i)! (i-1)!(n-k-i+1)!(n-k-r+i)!}
\]
or in
\[
\sum_{k=0}^{n+1} (1 + x)^k (1 + y)^{n-k} = \frac{(1 + y)^{n+1} - (1 + x)^{n+1}}{y - x} = \sum_{j=0}^{n+1} \binom{n+1}{j} (y^j - x^j) .
\]

Now the only summand which involves terms of degree \(r\) corresponds to \(j = r + 1\), so that the coefficient of \(x^i y^{r-i}\) in the sum is the coefficient in the single term
\[
\binom{n+1}{r+1} \frac{y^{r+1} - x^{r+1}}{y - x} .
\]
For each of the following expressions severally, determine as many integer values of \( x \) as you can so that it is a perfect square. Indicate whether your list is complete or not.

(a) \( 1 + x \);
(b) \( 1 + x + x^2 \);
(c) \( 1 + x + x^2 + x^3 \);
(d) \( 1 + x + x^2 + x^3 + x^4 \);
(e) \( 1 + x + x^2 + x^3 + x^4 + x^5 \).

**Solution.** (a) \( 1 + x \) is a square when \( x = u^2 - 1 \) for some integer \( u \) (or when \( x \) is the product of two integers \( u - 1 \) and \( u + 1 \) that differ by 2).

(b) **Solution 1.** Suppose that \( x^2 + x + 1 = u^2 \). Then \( (2x + 1)^2 + 3 = 4x^2 + 4x + 4 = 4u^2 = (2u)^2 \), whence

\[
3 = (2u)^2 - (2x + 1)^2 = (2u + 2x + 1)(2u - 2x - 1)
\]

The factors on the right must be \( \pm 3 \) and \( \pm 1 \) in some order, and this leads to the possibilities \( (x, u) = (-1, \pm 1), (0, \pm 1) \).

(b) **Solution 2.** If \( x > 0 \), then \( x^2 < x^2 + x + 1 < (x + 1)^2 \), so that \( x^2 + x + 1 \) cannot be square. If \( x < -1 \), then \( x^2 < x^2 + x + 1 > (x + 1)^2 \) and \( x^2 + x + 1 \) cannot be square. This leaves only the possibilities \( x = 0, -1 \).

(b) **Solution 3.** For given \( u \), consider the quadratic equation

\[
x^2 + x + 1 = u^2.
\]

Its discriminant is \( 1 - 4(1 - u^2) = 4u^2 - 3 \). It will have integer solutions only if \( 4u^2 - 3 = v^2 \) for some integer \( v \), i.e., \( (v + 2u)(v - 2u) = -3 \). The only possibilities are \( (u, v) = (\pm 1, \pm 1) \).
(b) Solution 4. [J. Chui] If \( f(x) = 1 + x + x^2 \), then \( f(x) = f(-(x+1)) \), so we need deal only with nonnegative values of \( x \). We have that \( f(0) = f(-1) = 1 \) is square. Let \( x \geq 1 \) and suppose that \( 1 + x + x^2 = u^2 \) for some integer \( u \). Then \( (1 + x)^2 = x > 0 \) so that \( 1 + x > u \). This implies that \( x \geq u \), whence \( x^2 \geq u^2 = x^2 + x + 1 \), a contradiction. Thus the only possibilities are \( x = 0, -1 \).

(b) Solution 5. [A. Birks] Suppose that \( x^2 + x + 1 = u^2 \) with \( u \geq 0 \). This is equivalent to \( x = (1 + x)^2 - u^2 = (1 + x + u)(1 + x - u) \), so that \( 1 + x + u \) and \( 1 + x - u \) both divide \( x \). If \( x > 1 \), then \( 1 + x + u \) exceeds \( x \) and so cannot divide \( x \). If \( x \leq 0 \), then \( -(x) + u - 1 \) divides \( x \), which is impossible unless \( u = 1 \) or \( u = 0 \). Only \( u = 1 \) is viable, and this leads to \( x = 0, -1 \).

(c) Solution. \( 1 + x + x^2 + x^3 = (1 + x^2)(1 + x) \). Let \( d \) be a common prime divisor of \( 1 + x \) and \( 1 + x^2 \). Then \( d \) must also divide \( (x - 1) = (1 + x^2) - (1 + x) \). Since \( \text{gcd}(x, x+1) = 1, d \) must divide \( x - 1 \) and so divide \( 2 = (x+1)-(x-1) \). Hence, the only common prime divisor of \( 1 + x^2 \) and \( 1 + x \) is \( 2 \).

Suppose \( 1 + x + x^2 + x^3 = (1 + x^2)(1 + x) \) is square. Then there are only two possibilities:

(i) \( 1 + x^2 = u^2 \) and \( 1 + x = v^2 \) for integers \( u \) and \( v \);

(ii) \( 1 + x^2 = 2r^2 \) and \( 1 + x = 2s^2 \) for integers \( r \) and \( s \).

\( Ad \) (i): \( 1 = u^2 - x^2 = (u - x)(u + x) \Rightarrow (x, u) = (0, \pm 1) \).

\( Ad \) (ii): We have \( x^2 - 2r^2 = -1 \) which has solutions \( (x, r) = (-1, 1), (1, 1), (7, 5), (41, 29), \ldots \). The complete set of solutions of \( x^2 - 2r^2 = \pm 1 \) in positive integers is given by \( \{(x_n, r_n) : n = 1, 2, \ldots \} \), where \( x_n + r_n\sqrt{2} = (1 + \sqrt{2})^n \), with odd values of \( n \) yielding solutions of \( x^2 - 2r^2 = -1 \). We need to select values of \( x \) for which \( x + 1 = 2s^2 \) for some \( s \). \( x = -1, 1, 7 \) work, yielding

\[
1 - 1 + (-1)^2 + (-1)^3 = 0 \\
1 + 1 + 1^2 + 1^3 = 2^2 \\
1 + 7 + 7^2 + 7^3 = 8 \times 50 = 20^2.
\]

There may be other solutions.

(d) Solution 1. Let \( f(x) = x^4 + x^3 + x^2 + x + 1 = (x^5 - 1)/(x - 1) \), with the quotient form for \( x \neq 1 \). We have that \( f(0) = f(-1) = 1^2 \) and \( f(3) = (243 - 1)/2 = 112^2 \). Also \( f(1) = 5 \) and \( f(2) = 31 \). Suppose that \( x \geq 4 \). Then \( x(x - 2) > 3 \), so that \( x^2 > 2x + 3 \). Hence

\[
(2x^2 + x + 1)^2 = 4x^4 + 4x^3 + 5x^2 + 2x + 1 \\
> 4x^4 + 4x^3 + 4x^2 + 4x + 4 = 4f(x)
\]

and

\[
4f(x) = (4x^4 + 4x^3 + x^2) + (3x^2 + 4x + 4) \\
= (2x^2 + x)^2 + (3x^2 + 4x + 4) > (2x^2 + x)^2.
\]

Thus, \( 4f(x) \) lies between the consecutive squares \((2x^2 + x)^2\) and \((2x^2 + x + 1)^2\) and so cannot be square. Hence \( f(x) \) cannot be square.

Similarly, if \( x \leq -2 \), then \( x(x - 2) > 3 \) and \( 3x^2 + 4x + 4 > 0 \), and we again find that \( 4f(x) \) lies between the consecutive squares \((2x^2 + x)^2\) and \((2x^2 + x + 1)^2\). Hence \( f(x) \) is square if and only if \( x = -1, 0, 3 \).

(d) Solution 2. [M. Boase] For \( x > 3 \),

\[
\left( x^2 + \frac{x}{2} \right)^2 < x^4 + x^3 + x^2 + x + 1 < \left( x^2 + \frac{x + 1}{2} \right)^2
\]
so that, lying between two half integers, \( x^4 + x^3 + x^2 + x + 1 \) is not square. Suppose \( x = -y \) is less than \(-1\). Since \( y - 1 < \frac{3}{4}y^2 \) and \( y^2 + 2y - 3 = (y + 3)(y - 1) > 0 \),

\[
(y^2 - \frac{y}{2})^2 < 1 - y + y^2 - y^3 + y^4 < \left(y^2 - \frac{y - 1}{2}\right)^2
\]

so again the middle term is not square. The cases \( x = -1, 0, 1, 2, 3 \) can be checked directly.

(e) Solution 1. Let

\[
g(x) = x^5 + x^4 + x^3 + x^2 + x + 1 = (x + 1)(x^4 + x^2 + 1) = (x + 1)((x^2 + 1)^2 - x^2) = (x + 1)(x^2 + x + 1)(x^2 - x + 1).
\]

Observe that \( g(x) < 0 \) for \( x \leq -2 \), so \( g(x) \) cannot be square in this case. Let us analyze common divisors of the three factors of \( g(x) \).

Suppose that \( p \) is a prime divisor of \( x + 1 \). Then

\[
x^2 + x + 1 = x(x + 1) + 1 \equiv 1 \mod p
\]

and

\[
x^2 - x + 1 = x(x + 1) - 2(x + 1) + 3 \equiv 3 \mod p.
\]

Hence \( \gcd(x + 1, x^2 + x + 1) = 1 \) and \( \gcd(x + 1, x^2 - x + 1) \) is either 1 or 3.

Suppose \( q \) is prime and \( x^2 + x + 1 \equiv 0 \) (mod \( q \)). Then \( x(x + 1) \equiv -1 \) (mod \( q \)), and \( x^2 - x + 1 \equiv -2x \) (mod \( q \)). Since \( x^2 + x + 1 \) is odd, \( q \neq 2 \), then \( x^2 - x + 1 \equiv 0 \) (mod \( q \)). Hence \( \gcd(x^2 + x + 1, x^2 - x + 1) = 1 \).

As we have seen from (b), \( x^2 + x + 1 \) is square if and only if \( x = -1 \) or 0. Indeed \( g(-1) = 0^2 \) and \( g(0) = 1^2 \). Otherwise, \( x^2 + x + 1 \) cannot be square. But \( \gcd(x^2 + x + 1, (x + 1)(x^2 - x + 1)) = 1 \), so \( g(x) \) cannot be a square either. Hence \( x^5 + x^4 + x^3 + x^2 + x + 1 \) is square if and only if \( x = -1 \) or 0.

(e) Solution 2. [M. Boase] Observe that \( x^5 + x^4 + \cdots + x + 1 = (x^3 + 1)(x^2 + x + 1) \). Since \( x^3 + 1 = (x^2 + x + 1)(x - 1) + 2 \), the greatest common divisor of \( x^3 + 1 \) and \( x^2 + x + 1 \) must divide 2. But \( x^2 + x + 1 = x(x + 1) + 1 \) is always odd, so the greatest common divisor must be 1. Hence \( x^2 + x + 1 \) and \( x + 1 \) both be square. Hence \( x \) must be either \(-1 \) or 0.

604. \( ABCD \) is a square with incircle \( \Gamma \). Let \( l \) be a tangent to \( \Gamma \), and let \( A', B', C', D' \) be points on \( l \) such that \( AA', BB', CC', DD' \) are all perpendicular to \( l \). Prove that \( AA' \cdot CC' = BB' \cdot DD' \).

Solution 1. Let \( \Gamma \) be the circle of equation \( x^2 + y^2 = 1 \) and let \( l \) be the line of equation \( y = -1 \). The points of the square must lie on the circle of equation \( x^2 + y^2 = 2 \). Let them be

\[
A \sim (\sqrt{2} \cos \theta, \sqrt{2} \sin \theta)
\]
\[
B \sim (-\sqrt{2} \sin \theta, \sqrt{2} \cos \theta)
\]
\[
C \sim (-\sqrt{2} \cos \theta, -\sqrt{2} \sin \theta)
\]
\[
D \sim (\sqrt{2} \sin \theta, -\sqrt{2} \cos \theta)
\]

for some angle \( \theta \) with \(-\pi/4 \leq \theta \leq \pi/4 \). Observe that \( 1/\sqrt{2} \leq \cos \theta \leq 1 \) and that \(-1/\sqrt{2} \leq \sin \theta \leq 1/\sqrt{2} \).

Then \( A' \sim (\sqrt{2} \cos \theta, -1), B' \sim (-\sqrt{2} \sin \theta, -1), C' \sim (-\sqrt{2} \cos \theta, -1) \) and \( D' \sim (\sqrt{2} \sin \theta, -1) \), so that \( AA' = 1 + \sqrt{2} \sin \theta, BB' = 1 + \sqrt{2} \cos \theta, CC' = 1 - \sqrt{2} \sin \theta \) and \( DD' = 1 - \sqrt{2} \cos \theta \). Hence

\[
AA' \cdot CC' - BB' \cdot DD' = (1 + \sqrt{2} \sin \theta)(1 - \sqrt{2} \sin \theta) - (1 + \sqrt{2} \cos \theta)(1 - \sqrt{2} \cos \theta)
\]
\[
= (1 + \sqrt{2} \sin \theta)(1 - \sqrt{2} \sin \theta) + (1 + \sqrt{2} \cos \theta)(1 - \sqrt{2} \cos \theta)
\]
\[
= 1 - 2 \sin^2 \theta + 1 - 2 \cos^2 \theta = 0.
\]
Solution 2. One can proceed as in the first solution, taking the four points on the larger circle at the intersection with the perpendicular lines \( y = mx \) and \( y = -x/m \). The points are

\[
A \sim \left( \frac{\sqrt{2}}{\sqrt{m^2 + 1}}, \frac{m\sqrt{2}}{\sqrt{m^2 + 1}} \right) \quad B \sim \left( \frac{-m\sqrt{2}}{\sqrt{m^2 + 1}}, \frac{\sqrt{2}}{\sqrt{m^2 + 1}} \right)
\]

\[
C \sim \left( \frac{\sqrt{2}}{\sqrt{m^2 + 1}}, \frac{-m\sqrt{2}}{\sqrt{m^2 + 1}} \right) \quad D \sim \left( \frac{m\sqrt{2}}{\sqrt{m^2 + 1}}, \frac{-\sqrt{2}}{\sqrt{m^2 + 1}} \right).
\]

In this case, the products turn out to be equal to \( |(m^2 - 1)/(m^2 + 1)| \).

Solution 3. [A. Birka] Let the circle have equation \( x^2 + y^2 = 1 \) and the square have vertices \( A \sim (1, 1), \quad B \sim (-1, 1), \quad C \sim (-1, -1), \quad D \sim (1, -1) \). Suppose, wolog, that the line \( l \) is tangent to the circle at \( P(t, \sqrt{1-t^2}) \) with \( 0 < t < 1 \) and intersects \( CB \) produced in \( Y \) and \( AD \) in \( X \). The line \( l \) has equation \( tx + \sqrt{1-t^2}y = 1 \) and so the coordinates of \( X \) are \( (1, u) \) and of \( Y \) are \( (-1, 1/u) \) where \( u = (1-t)/\sqrt{1-t^2} \). Now \( YB : YC = (1-u) : (1+u) = AX : XD \). Since \( \Delta YBB' \) is similar to \( \Delta YCC' \) and \( \Delta XAA' \) is similar to \( \Delta XDD' \),

\[
BB' : CC' = YB : YC = AX : XD = AA' : DD',
\]

and the result follows.

Comment. If the circle has equation \( x^2 + y^2 = r^2 \), the square has vertices \( (\pm r, \pm r) \) and the line through a point \( (a, b) \) on the circle has equation \( ax + by = r^2 \), then the distance product is \( 2ab \).
