NON-RADIA LLY SYMMETRIC SOLUTIONS
TO THE GINZBURG-LANDAU EQUATION *

by

Yu. N. Ovchinnikov¹ and I.M. Sigal²

Abstract. We consider the question of existence of non-radical solutions to Ginzburg-Landau equation. We present results indicating that such solutions do exist. We look for such solutions as saddle points of the renormalized Ginzburg-Landau free energy functional (the latter was introduced in reference [OS1]). There are two main points in our analysis: we look for solutions having certain point symmetries and we characterize saddle point solutions in terms of critical points of certain intervortex energy function which we introduce. The latter critical points correspond to forceless vortex configuration.

1. Introduction

The Ginzburg-Landau equation arises in condensed matter physics and nonlinear optics. It is commonly used in Physics. Though it is of an extremely simple form it is still poorly understood in spite of a considerable progress in recent years (see e.g. [A, BBH1,2, BMR, CK, LL, M1,2, OS1, PR, R, S]). We still do not know whether this equation in \( \mathbb{R}^2 \) has any solutions other than the vortex ones. It is the aim of this article to present an argument, partly rigorous, partly not, that this equation possess a rich set of solutions with point symmetries. Thus in this paper we consider the equation

\[-\Delta \psi + (|\psi|^2 - 1)\psi = 0 , \tag{1.1}\]

where, in the simplest and most important case considered in this paper, \( \psi : \mathbb{R}^2 \to \mathbb{C} \), with the boundary condition

\[
|\psi| \to 1 \quad \text{as} \quad |x| \to \infty .
\]  

(1.2)

So far only radially symmetric solutions, i.e. solutions of the form \( \psi_n(x) = f_n(r)e^{in\theta} \), where \( r \) and \( \theta \) are polar coordinates for \( x \in \mathbb{R}^2 \), are known for (1.1)–(1.2) (see [GP, H, HH, CEQ, FP, OS1, CK, M1,2, LL]). Solutions \( \psi_n \) are called the \( n \)-vortices. Note that \( n = \text{deg}\psi_n \). Here \( \text{deg}\psi \), the degree (or vorticity) of \( \psi \) (satisfying (1.2)), is the total index (winding number) of \( \psi \), considered as a vector field on \( \mathbb{R}^2 \), at \( \infty \), i.e.

\[
\text{deg} \, \psi := \frac{1}{2\pi} \int_{|x|=R} d(\text{arg} \, \psi)
\]

for \( R \) sufficiently large.

Existence and properties of the vortex solutions were established only recently. What we know now is

(i) Existence and uniqueness (modulo symmetry transformations and in the class of radially symmetric functions) ([HH, CEQ, FP, OS1])

(ii) Stability for \( |n| \leq 1 \) and instability for \( |n| > 1 \) ([OS1], earlier results on stability for the disc are due to [LL, M1])

(iii) Uniqueness of \( \psi_{\pm 1} \) (again, modulo symmetry transformation) in the class of functions, \( \psi \), with \( \text{deg}\psi = \pm 1 \) and obeying \( \int (|\psi|^2 - 1)^2 < \infty \) ([M2]).

Thus the next question is are these non-radially symmetric solutions?

In this paper we present results indicating that such solutions do exist. There are two key ingredients in our analysis. Firstly, we characterized non-radially symmetric solutions as critical points of the intervortex energy function described below (see also [OS2]). Secondly, we look for solutions having certain point symmetries. The latter fact reduces the
number of free parameters describing such solutions to one (the size of the corresponding polygon of vortices).

Solution breaking rotational symmetry were found to exist in the case of the Ginzburg-Landau equation in the ball \( B_R = \{ x \in \mathbb{R}^2 \mid |x| \leq R \} \) with the boundary condition \( \psi|_{\partial B_R} = e^{in\theta} \) and \( |n| \geq 2 \) (see [BBH, Thm IX.1]). However, in the case of the ball there is an external mechanism leading to the symmetry breaking: the boundary condition. The latter repels vortices forcing their confinement. On the other hand the energy is lowered by breaking up multiple vortices into \( +1 \) - (or \(-1\) -) vortices and merging vortices of opposite signs. Thus for \( R \) not so small the lowest energy is reached by a configuration of \( |n| \) vortices of vorticities \( \pm 1 \) depending on the sign of \( n \) which, obviously, is not rotationally symmetric.

The paper is organized as follows. In Sections 2–3 we review some material from [OS1]: the variational formulation of the problem and some specific properties of the vortex solutions. In Section 4 we define the intervortex energy and discuss its properties. In particular we discuss the correlation term in the (upper bound on) expansion of the intervortex energy for large intervortex separations and a definition of \( G \)-symmetric vortex energies, where \( G \) is a subgroup of the symmetry group of (1.1)

In Section 5 we consider point symmetries \( (C_{Nv}) \), present one of our main results, Theorem 5.1, on existence of critial points for \( C_{Nv} \)-symmetric intervortex energies and derive some general relations for those energies. In Section 6 we prove Theorem 5.1 and present a discussion of some other cases.

Finally, we have five appendices where all the hard analytical and numerical work is concentrated. In these appendices we compute various asymptotic expansions beyond the leading order. We feel that these appendices are of interest on their own as they address
rather subtle computational issues.

2. Renormalized Ginzburg-Landau energy

It is a straightforward observation that Eqn (1.1) is the equation for critical points of the following functional

\[ \mathcal{E}(\psi) = \frac{1}{2} \int \left( |\nabla \psi|^2 + \frac{1}{2}(|\psi|^2 - 1)^2 \right). \]  \hfill (2.1)

Indeed, if we define the variational derivative, \( \partial_\psi \mathcal{E}(\psi) \), of \( \mathcal{E} \) by

\[ \text{Re} \int \xi \partial_\psi \mathcal{E}(\psi) = \left. \frac{\partial}{\partial \lambda} \mathcal{E}(\psi_\lambda) \right|_{\lambda=0} \]  \hfill (2.2)

for any path \( \psi_\lambda \) s.t. \( \psi_0 = \psi \) and \( \left. \frac{\partial}{\partial \lambda} \psi_\lambda \right|_{\lambda=0} = \xi \), then the l.h.s. of Eqn (1.1) is equal to \( \partial_\psi \mathcal{E}(\psi) = \partial_\psi \mathcal{E}(\psi) \) for \( \mathcal{E}(\psi) \) given in (2.1).

(2.1) is the celebrated Ginzburg-Landau (free) energy. However, there is a problem with it in our context. It is shown in [OS1] that if \( \psi \) is an arbitrary \( C^1 \) vector field on \( \mathbb{R}^2 \) s.t. \( |\psi| \to 1 \) as \( |x| \to \infty \) uniformly in \( \hat{x} = \frac{x}{|x|} \) and \( \text{deg} \psi \neq 0 \), then \( \mathcal{E}(\psi) = \infty \).

We renormalize the Ginzburg-Landau energy functional as follows (see [OS1]). Let \( \chi(x) \) be a smooth positive function on \( \mathbb{R}^2 \) vanishing at the origin and converging to one at infinity. Define

\[ \mathcal{E}_{\text{ren}}(\psi) = \frac{1}{2} \int \left( |\nabla \psi|^2 - \frac{(\text{deg} \psi)^2}{r^2} \chi + F(|\psi|^2) \right) d^2 x \]  \hfill (2.3)

where

\[ F(u) = \frac{1}{2} (u - 1)^2. \]  \hfill (2.4)

Properties of the renormalized energy functional, \( \mathcal{E}_{\text{ren}}(\psi) \), are investigated in [OS1].

In this paper we take

\[ \chi(x) = \begin{cases} 
1 & \text{for } |x| \geq R + R^{-1}, \\
0 & \text{for } |x| \leq R 
\end{cases} \]  \hfill (2.5)
for $R$ very large large compared to all length scales appearing below.

3. Vortices

It is shown in [HH, CEQ, FP, OS1] that for any any $n$, Eqn (1.1) has a solution, unique modulo symmetry transformations, of the form

$$
\psi_n(x) = f_n(r)e^{in\theta},
$$

where $1 > f_n \geq 0$ and is monotonically increasing from $f_n(0) = 0$ to $1$ as $r$ increases to $\infty$. For $n = 0$, $f_n(r) = 1$. For $|n| > 0$, $f_n(r)$ does not admit an explicit expression. These are the $n$-vortices mentioned in the introduction. Of course, each solution $\psi_n$ generates a one-parameter for $n = 0$ and a three-parameter for $|n| > 0$ family of solutions of (1.1). The latter are obtained by applying symmetry transformations to $\psi_n$.

The function $f_n(r)$ in (3.1) satisfies the ordinary differential equation

$$
-\frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial f_n}{\partial r}\right) + \frac{n^2}{r^2} f_n - (1 - f_n^2)f_n = 0.
$$

The (self) energy of the $n$-vortex is given by $E_{n,R} := \mathcal{E}_{\text{ren}}(\psi_n)$. To compute $E_{n,R}$ we use that if $\psi$ is a solution to (1.1), then, due to the integration by part formula $\int |\nabla \psi|^2 = -\int \bar{\psi} \Delta \psi$, we have

$$
\mathcal{E}_{\text{ren}}(\psi) = \frac{1}{2} \int \left(1 - |\psi|^2 - \frac{1}{2}(1 - |\psi|^2)^2 - \frac{(\text{deg} \psi)^2}{r^2} \chi \right).
$$

Using this formula for $\psi = \psi_n$ and using the asymptotic expression (this can be easily derived from (3.2), in the general case see [S, OS4])

$$
f_n(r) = 1 - \frac{n^2}{2r^2} + O\left(\frac{1}{r^4}\right)
$$

for $r \gg 1$, we obtain

$$
E_{n,R} = \pi n^2 \ln \left(\frac{R}{|n|}\right) + c(|n|) + O\left(\frac{1}{R^2}\right).
$$
The constant $c(n)$ can be computed numerically (which is not quite trivial, see Appendix 1) which yields

$$c(1) = 0.376 \pi, \quad c(2) = 0.535 \pi, \quad c(3) = 0.577 \pi, \quad c(5) = 0.615 \pi. \quad (3.6)$$

The asymptotics of $c(n)$ for $n \gg 1$ is found analytically in Appendix 2.

4. Intervortex energy

In this section we introduce and discuss a key concept of the intervortex energy (see also [OS3,5]). We begin with some definitions.

By a vortex configuration, $\zeta$, we will understand a pair $(a, \mathbf{n})$, where $a = (a_1, \ldots, a_K)$, $a_j \in \mathbb{R}^2$, and $\mathbf{n} = (n_1, \ldots, n_K)$, $n_j \in \mathbb{Z}$, for some $K \geq 1$ (positions of the vortex centers and their vorticities). Consider once differentiable functions $\psi: \mathbb{R}^2 \to \mathbb{C}$ satisfying $|\psi| \to 1$ as $|x| \to \infty$. We say that the vortex configuration of $\psi$ is $\zeta = (a, \mathbf{n})$, $\text{conf } \psi = \zeta$, if $\psi$ has zeros (only) at $a_1, \ldots, a_K$ with local indices $n_1, \ldots, n_K$, respectively, i.e.

$$\int_{\gamma_j} d(\arg \psi) = 2\pi n_j$$  \hspace{1cm} (4.1)

for any contour $\gamma_j$ containing $a_j$, but not the other zeros of $\psi$, and for $j = 1, \ldots, K$. (Strictly speaking we have to specify the phase-factor, or rotation angle, for each vortex; but these will play no role in our considerations and are not displayed or mentioned in what follows.) Now we define

$$E_R(\zeta) = \inf \left\{ \mathcal{E}_{\text{ren}}(\psi) \mid \text{conf } \psi = \zeta \right\}. \quad (4.2)$$

where the parameter $R$ comes from (2.5). We expect that $E_R(\zeta) > -\infty$. An argument supporting this statement is somewhat lengthy and will be presented elsewhere (see [OS5]). Of course, for bounded domains, this inequality is trivial. We call $E_R(\zeta)$ the energy of the
vortex configuration $\mathcal{C}$. It will play a central rôle in our analysis. Note also that $E(\mathcal{C})$ serves as a Hamiltonian for the vortex dynamics in the adiabatic approximation (see [OS2]).

In what follows we keep the vortex indices $\mathbb{n}$ fixed and write $E_R(\mathbb{a})$ for $E_R(\mathcal{C})$. It is clear intuitively that a minimizer in (4.2) exists if and only if $\nabla E_R(\mathbb{a}) = 0$ (the force acting on the vortex centers is zero). However, to establish this fact is not so easy.

**Theorem 4.1.** If there is a minimizer for variational problem (4.2), then this minimizer satisfies Ginzburg-Landau equation (1.1).

**Proof.** Let $\psi$ be a minimizer for (4.2). Since for any differentiable function $\xi: \mathbb{R}^2 \to \mathbb{C}$ vanishing together with its gradient sufficiently fast at $\infty$ and vanishing at the points $a_1, \ldots, a_m$ we have

$$0 = \frac{\partial}{\partial \lambda} \mathcal{E}_{\text{ren}}(\psi + \lambda \xi) \bigg|_{\lambda=0} = \text{Re} \int \bar{\xi} (\Delta \psi + (|\psi|^2 - 1) \psi) ,$$

we conclude that $\psi$ satisfies (1.1) for $x \neq a_1, \ldots, a_m$. On the other hand, since $\psi \in H^1_{\text{loc}}(\mathbb{R}^2)$, we have that $-\Delta \psi + (|\psi|^2 - 1) \psi \in H^1_{\text{loc}}(\mathbb{R}^2)$. Hence $-\Delta \psi + (|\psi|^2 - 1) \psi = 0$ on $\mathbb{R}^2$. \hfill \Box

**Conjecture 4.2.** $\nabla E_R(\mathbb{a}_0) = 0$ for some $\mathbb{a}_0$ (remember $\mathbb{n}$ is fixed) if and only if there is a minimizer for problem (4.2) at the configuration $\mathbb{a}_0$ and consequently, due to Theorem 4.1, if and only if Ginzburg-Landau equation (1.1) has a solution with the configuration $\mathbb{a}_0$.

The goal of this paper is to find forceless vortex configurations, i.e. configurations $\mathcal{C}$ s.t.

$$\nabla E_R(\mathbb{a}) = 0 \ .$$

(4.3)

To this end we study the intervortex energy $E_R(\mathbb{a})$ for very small and very large intervortex separations.
Let $d_a = \min_{i \neq j} |a_i - a_j|$ for $a = (a_1, \ldots, a_K)$. For $d_a$ large we prove in Section 7 the following upper bound

$$E_R(a) \leq E_R^{(0)} - A(a) + O(d_a^{-8/3}) + O(R^{-2}) ,$$

(4.4)

where $E_R^{(0)} = \sum_{i=1}^K E_{n_i,R} + H \left( \frac{a}{R} \right)$, and $A(a)$ is a homogeneous function of degree $-2$, provided $a$ satisfies $\nabla H(a) = 0$. Here, recall, $E_{n,R} = E_{\text{ren}}(\psi_n)$ is the self-energy of the $n$-vortex (see (3.5)) and $H(a)$ is the energy of the vortex pair interactions,

$$H(a) = -\pi \sum_{i \neq j} n_i n_j \ln |a_{ij}| ,$$

(4.5)

with $a_{ij} = a_i - a_j$.

The correlation term $A(a)$ is of importance for us here. We have an explicit expression for it, see Eqns (A3.4)-(A3.5), and compute it explicitly in the cases of interest. We conjecture that $A(a) > 0$ always.

Observe that upper bound (4.4) with the remainder $O(d_a^{-1})$ instead of $-A(a) + O(d_a^{-8/3})$ is obtained by choosing the Hartree-type function $\psi^{(0)}(x) = \prod_{i=1}^K \psi_{n_i}(x - a_i)$ describing “independent” vortices. For asymptotically forceless configurations, i.e. the ones with $\nabla H(a) = 0$, this estimate can be somewhat improved, but in order to move even to the remainder estimate $O(d_a^{-2} \ln d_a)$ in the latter case, one has to refine upon this function and include the leading correlations.

**Remark 4.3.** As $d_a \to \infty$, the following important asymptotic expression was demonstrated in [OS5]

$$E_R(a) = \sum_{i=1}^K E_{n_i,R} + H \left( \frac{a}{R} \right) + \text{Rem} ,$$

(4.6)

where $\text{Rem} = O(d_a^{-2} \ln d_a)$ in general and $= O(d_a^{-2})$ if $\nabla H(a) = 0$, as $d_a \to \infty$.

As mentioned in the introduction, our second idea is to consider solutions to (1.1) invariant under point groups transformation. Consequently, we introduce intervortex en-
ergy functions invariant under such groups. Consider a subgroup $G$ of the total symmetry group

$$G_{\text{sym}} = O(2) \times T(2) \times U(1)$$

($T(n)$ is the group of translations of $\mathbb{R}^n$) of Ginzburg-Landau equation (1). For a $G$-invariant vortex configuration $\zeta = (a, n)$ (i.e. invariant under the spatial part of $G$) we define $G$-invariant vortex interaction energy $E_{R,G}(a)$ as

$$E_{R,G}(a) = \inf\{\mathcal{E}_{\text{ren}}(\psi) | \text{conf} \psi = \zeta, \psi \text{ is } G\text{-invariant}\}$$

(as before we fix $n$ and omit it from the relation).

Theorem 4.1 and Conjecture 4.2 extend obviously to the $G$-symmetric situation. In particular we have the following conjecture:

If $a_0$ is a critial point of $E_{R,G}(a)$ (i.e. $\nabla E_{R,G}(a_0) = 0$), then (1.1) has a $G$-invariant solution.

Our goal in what follows is, for appropriate groups $G$, namely, point groups $C_{Nv}$ (see the next section), to find critial points of the $G$-invariant intervortex energy $E_{R,G}(a)$.

5. Point symmetries

We look for solutions of Eqn (1.1) having symmetry groups, $C_{Nv}$. These groups consist of rotations around the origin by angles a multiple of $\frac{2\pi}{N}$ and reflection(s) in one (and therefore $N$) line(s) through the origin. Such solutions are determined by fixing vortex configurations having the desired symmetry group. We consider vortex configurations consisting of $N$ $m$-vortices uniformly spaced on a circle of radius $a$ and a single ($-k$)-vortex in the center of the circle, which is placed at the origin. Several such configurations and their symmetry lines are shown in Fig. 1.
Fig. 1. Symmetric configurations and their reflection lines

Such configurations have the symmetry group $C_{Nv}$. On the other hand, the symmetry group $C_{Nv}$ determines such a configuration uniquely up to the vortex values $m$ and $k$ and the size $a$.

As was pointed out at the end of the previous section we rely on the argument that $C_{Nv}$-symmetric solutions are in one-to-one correspondence with critical points of the $C_{Nv}$-symmetric intervortex energy

$$E_R(c) \equiv E_{R,C_{Nv}}(c)$$

(here and in what follows we consider only $C_{Nv}$-symmetric intervortex energies and we often omit the subindex $C_{Nv}$). Thus our goal is to find critical points of $E_R(c)$. One of the central results of this paper is the following

**Theorem 5.1.** There exist minima of $E_{R,C_{Nv}}(c)$ among the configurations, $c$, described above for the following values of the parameters

$$(N, m, k) = (2, 2, 1) \text{ and } (4, 2, 3)$$
(see Fig. 1, a critical value of the parameter \( a \) is not specified, but its existence is established).

This theorem is proven in Section 6. In the rest of this section we establish general properties of the energy \( E_{R,C_{N_v}}(\mathcal{C}) \) and find a necessary condition on the parameters \( N \), \( m \) and \( k \).

Observe that if \( \mathcal{C} \) is a configuration described above, then (again we do not display the parameters \( n \))

\[
\nabla_{a_j} E_R(a) = \hat{a}_j \partial_{|a_j|} E_R(a) \quad \text{and} \quad \nabla_{a_j} H(a) = \hat{a}_j \partial_{|a_j|} H(a) \quad \forall j ,
\]

(5.1)

where \( \hat{a} = a/|a| \). Thus in this case it suffices to investigate the energy \( E_R(\hat{a}) \) as a function of one variable, scale parameter \( a \).

Note that if \( m \geq 2 \), then there is a continuum of configurations, labeled by a parameter \( \alpha > 0 \), with the same symmetry group, say \( C_{N_v} \), as a given configuration, which have the given configuration as a limit as \( \alpha \to 0 \). For instance, for \( m = 2 \), each \( m \)-vortex can be split into a pair of \( 1 \)-vortices with all pairs lying either on the circle or on the lines joining their parent \( m \)-vortices to the origin, at equal distance, \( \alpha \), to those \( m \)-vortices (see Fig. 2)

By symmetry, the energy of the resulting configurations has a critical point at \( \alpha = 0 \). A simple analysis of the break-up of a 2-vortex shows that this critical point is a local maximum. Indeed, e.g., for \( m = 2 \), it was shown in [OS1] that the linearization of Eqn
(1.1) (= the Hessian of the energy functional) around the 2-vortex solutions \( \psi_2 = f_2(r)e^{2i\theta} \) has exactly one negative mode (= an eigenfunction corresponding to a negative eigenvalue) of the form \( \xi = e^{4i\phi}\xi_4(r) + \xi_0(r) \), where \( \xi_k(r) \) are some real functions. Then the function \( \psi_2 + \lambda \xi \) for \(|\lambda|\) sufficiently small lowers the energy of \( \psi_2 \). On the other hand this function has two simple zeros (i.e. of vorticities +1) in a vicinity of \( x = 0 \). Indeed, in the complex notation \( z = x_1 + x_2 \leftrightarrow x = (x_1, x_2) \), \( \psi_2(z) = bz^2 + O(z^3) \), while \( \xi(z) = c + O(z) \), for some positive numbers \( b \) and \( c \), in a neighbourhood of \( z = 0 \). Hence \( \psi_2(z) + \lambda \xi(z) = bz^2 + \lambda c + O(z^3) + O(\lambda z) \) and therefore has two simple zeros \( z_\pm = \pm \sqrt{\frac{\lambda c}{b}} + O(\lambda z) \) in a neighbourhood of \( z = 0 \). This shows in particular that splitting of a 2-vortex lowers the energy.

**Proposition 5.2.** Let a configuration \( c_0 \), as described above, be asymptotically forceless, i.e. \( \nabla H(c_0) = 0 \). Then

\[
k = \frac{1}{2}(N - 1)m .
\]  

**Proof.** By (4.1), the equation \( \nabla H(c_0) = 0 \) for the configuration described is equivalent to the equation

\[
\frac{\partial}{\partial a}H(a) = 0 .
\]  

Since

\[
H(a) = H\left(\frac{a}{\tilde{a}}\right) - \pi \sum_{i \neq j} n_i n_j \ln a ,
\]  

the latter equation implies that \( \sum_{i \neq j} n_i n_j = 0 \), which, due to the relation

\[
\sum_{i \neq j} n_i n_j = -2Nm + N(N - 1)m^2 ,
\]

is equivalent to (5.2). □

Note that Eqn (5.3) implies that if \( \nabla H(a_0) = 0 \) then \( \nabla H(a) = 0 \) for all \( a \)'s of the form \( a = sa_0 \), \( s > 0 \). The latter fact implies another proof of (5.2). Indeed, \( H\left(\frac{a}{\tilde{a}}\right) \) behaves
for large $R$ as $\text{const} \cdot \ln R + \text{const}$. Hence for the asymptotically force-free configuration (i.e. the one with $\nabla H(a) = 0$) the constant in front of $\ln R$ is independent of the scale parameter $a$. This asymptotic scale invariance implies that the leading term,

$$\pi(Nm - k)^2 \ln R,$$

for the configuration with $a = 0$, i.e. when all the vortices collapse onto the center of the circle, is equal to the leading term,

$$\pi(Nm^2 + k^2) \ln R,$$

for the configuration with a very large $a$ so that the vortices in such a configuration can be treated as virtually independent (see (4.4)). Hence

$$(Nm - k)^2 = Nm^2 + k^2,$$

which implies (5.2).

Observe that Eqn (5.2) is equivalent to the relation

$$H\left(\frac{a}{R}\right) = H\left(\frac{a}{a}\right) = H(a), \quad \text{independent of } a. \quad (5.6)$$

Indeed, this follows from Eqns (5.4) and (5.5).

Relation (5.2) between $k$ and $m$ will be assumed from now on.

Now for the configuration above we introduce the energy differences

$$\Delta E(a) := E_R(a) - \pi(Nm - k)^2 \ln R \quad (5.7)$$

(remember that $Nm - k$ is the total vorticity of the configuration in question). Recall that $E_{n,R}$ denotes the energy of a single vortex of vorticity $n$, i.e. $E_{n,R} = \mathcal{E}_\text{ren}(\psi_n)$. Denote the energy difference for this vortex by $\Delta E_n$:

$$E_{n,R} = \pi n^2 \ln R + \Delta E_n. \quad (5.8)$$
Clearly

\[ E_R(0) = E_{N m, k, R} \quad \text{and} \quad \Delta E(0) = \Delta E_{N m, k} . \] (5.9)

This together with (3.5) implies (modulo \( O(R^{-2}) \)) that

\[ \Delta E(0) = -\pi (N m - k)^2 \ln(N m - k) + c(N m - k) . \] (5.10)

On the other hand, for the intervortex distances very large, Eqns (5.7), (5.6), (4.6) and (3.5) imply (modulo \( O(R^{-2}) + o(a^{-2}) \))

\[ \Delta E(a) \leq -\pi (N m^2 \ln m + k^2 \ln k) + N c(m) + c(k) + H(a) - C a^{-2} , \] (5.11)

where \( C = A(a/a) \). Compute \( H(a) \) for the configuration at hand. Since the distances between the vortices on the circle are \( 2a \sin \frac{\pi}{N}, 2a \sin \frac{2\pi}{N}, \ldots, 2a \sin \frac{(N-1)\pi}{N} \), we find

\[ H(a) = -\pi m^2 N \sum_{k=1}^{N-1} \ln \left( 2 \sin \frac{k\pi}{N} \right) . \] (5.12)

This equation together with Eqn (5.11) yields, modulo \( O(R^{-2}) + o(a^{-2}) \), that for large intervortex distances

\[ \Delta E(a) \leq -\pi (N m^2 \ln m + k^2 \ln k) + N c(m) + c(k) \]

\[ -\pi m^2 N \sum_{k=1}^{N-1} \ln \left( 2 \sin \frac{k\pi}{N} \right) - C a^{-2} . \] (5.13)

In the next section we establish existence of points \( a_0 \) s.t. \( \nabla E(a_0) = 0 \) for given configurations, by comparing \( \Delta E(0) \) and \( \Delta E(a) \), for large intervortex distances \( a \).

6. The simplest cases. Proof Theorem 5.1

In this section we consider some special, in fact the simplest, cases of the vortex configurations introduced in Section 5. Recall that the latter consists of a vortex of vorticity
$-k$ sitting at the origin and $N$ vortices, each of vorticity $m$, distributed equidistantly on
the circle of radius $a$ with the center at the origin. Such a configuration will be fixed by
the symmetry group $C_{Nv}$, so that the only remaining free parameter is the radius of the
circle $a$. Thus, we denote, with a slight abuse of notation, $\Delta E(a) = \Delta E(a)$.

**Proof of Theorem 5.1.** The correlation coefficient, $C$, in Eqn (5.13), is computed
for the configurations of interest in Appendix 3:

\[ C = 8\pi, \quad 80\pi \text{ for } (N, m, k) = (2, 2, 1), (4, 2, 3). \quad (6.1) \]

(We suspect that for general $(N, m, k)$, $k = \frac{1}{2}(N - 1)m$, $C$ is of the form $\frac{\pi}{4} \cdot \text{integer}$.)

Thus

\[ \Delta E(a) \text{ monotonically increases to } \Delta E(\infty) \text{ as } a \to \infty. \quad (6.2) \]

Moreover due to (3.6), we have

\[ \Delta E(\infty) < \Delta E(0), \quad (6.3) \]

again for the configurations $(N, m, k) = (2, 2, 1), (4, 2, 3)$ (explicit computations are given
below). Hence $\Delta E(a)$ has at least one minimum for those configurations as claimed.

**Computation of (6.3).**

(a) The case $N = 2$, $m = 2$ and $k = 1$ (recall, $E_R(a) \equiv E_R(a)$, etc.) We have

\[ \Delta E(0) \equiv \Delta E_3(0) = c(3) - 9\pi \ln 3 = -9.31\pi. \quad (6.4) \]

On the other hand, Eqn (5.11) implies that for $a$ very large

\[ \Delta E(a) \leq c(1) + (2c(2) - 8\pi \ln 2) - 8\pi \ln 2 - Ca^{-2} + O\left(\frac{\ln a}{a^4}\right) \]

\[ = -9.64\pi - Ca^{-2} + O\left(\frac{\ln a}{a^4}\right). \quad (6.5) \]

(b) The case $N = 4$, $m = 2$ and $k = 3$ (see Fig. 1). In this case

\[ \Delta E(0) = \Delta E_5(0) = c(5) - 25\pi \ln 5 = -39.62\pi. \quad (6.6) \]
On the other hand, Eqn (5.11) implies that for large $a$ we have the following asymptotic behaviour

$$
\Delta E(a) \leq \left(4c(2) - 16\pi \ln 2\right) + \left(c(3) - 9\pi \ln 3\right) - 32\pi \ln 2 - Ca^{-2} + O\left(\frac{\ln a}{a^4}\right)
$$

(6.7)

$$
= -40.44\pi - Ca^{-2} + O\left(\frac{\ln a}{a^4}\right).
$$

Thus (6.3) is shown. \(\square\)

**Remarks. a.** Examine the case of $m = 1$, i.e. the vortices on the circle are simple. In this case $k = \frac{1}{2}(N-1)$. Thus in the simplest case $N = 3$ and $k = 1$ we take the $(m = 1)$-vortices equally spaced (Fig. 3).

![Fig. 3.](image)

Eqns (4.9), (4.12) and (3.6) yield that in this case $\Delta E(0) < \Delta E(\infty)$ (in fact, $\Delta E(0) = \Delta E_2(0) = -2.238\pi$ and $\Delta E(\infty) = -1.792\pi$). Numerical computations show (see Appendices 3 and 4) that $\Delta E'(\infty) > 0$ and $\Delta E'(0) > 0$ (in fact, for $a \gg 1$, $\Delta E(a) = 4c(1) - 3\pi \ln 3 - Ca^{-2} = -1.792\pi - Ca^{-2}$ with $C > 0$). Thus we cannot conclude existence of a critical point for $E_R(a)$ in this case. However, a more careful numerical analysis indicates that, probably, there exist two extremal points of $E_R(a)$, one minimum and another maximum, for $\frac{1}{\sqrt{2}} \leq a \leq 2$. Similar configurations for $N$ large (and odd) are analyzed in Appendix 5.

**b.** The case $N = 2, m = 2$ and $k = 1$, is the limiting case of $N = 4, m = 1$ and $k = 1$ (see Fig. 2). All three configurations have the same symmetry group, $C_{2v}$: rotation by $\pi$ and reflections in the vertical and horizontal axes passing through the vortex $-1$. After
the symmetry group is fixed, the second and third configurations have two free parameters: the scale parameter \( a \) and the angle/distance, \( \alpha \), between two of its neighbouring 1-vortices (see Fig. 3). As \( \alpha \to 0 \), the second and third configurations are continuously transformed into the first one.

7. Upper bound on the intervortex energy

In this section we prove inequality (4.4) for the energy, \( E_R(a) \), of vortex configurations. Namely we prove

**Theorem 7.1.** We have the estimate

\[
E_R(a) \leq E_R^{(0)} + \text{Rem} + O(\max |a_j|^2/R^2) ,
\]

where \( E_R^{(0)} = \sum_{k=1}^{k} E_{n_k, R} + H(\frac{a}{R}) \), and

\[
\text{Rem} = \begin{cases} 
O(d_a^{-2}) & \text{if } \nabla H(a) = 0 \\
O(d_a^{-2} \ln d_a) & \text{otherwise}
\end{cases}
\]

Moreover, if \( \nabla H(a) = 0 \), then estimate (7.2) can be improved as

\[
\text{Rem} = -A(a) + O(d_a^{-\frac{3}{2}}) + O\left(\frac{1}{R^2}\right) ,
\]

where \( A(a) \), the correlation term, is a homogeneous degree \(-2\) function, explicitly given by the following conditionally convergent integral

\[
A(a) = \frac{1}{4} \int \left[ |\nabla \varphi_0|^4 - \sum_j |\nabla \varphi_j|^4 \right]
\]

(\( \nabla H(a) = 0 \) is assumed) with

\[
\varphi_0 = \sum_j \varphi_j \quad \text{and} \quad \varphi_j(x) = n_j \theta(x - a_j) ,
\]

\( \theta(x) = \text{the polar angle of } x \in \mathbb{R}^2 \).
**Proof.** We prove the upper bound (7.1) by using the variational inequality

\[ E_R(a) \leq \mathcal{E}_{\text{ren}}(\psi) , \quad (7.6) \]

valid for any function \( \psi \) having the given vortex configuration \( a \), and by showing that for an appropriate \( \psi \), \( \mathcal{E}_{\text{ren}}(\psi) \) is of the form of the r.h.s. of (7.6). Namely we show that

\[ \mathcal{E}_{\text{ren}}(\psi) = E_R^{(0)} + \text{Rem} , \quad (7.7) \]

where \( \text{Rem} \) is given by either (7.2) or (7.3), as appropriate. Then (7.1) follows from (7.6) and (7.7).

Before proceeding to a proof of these estimates, we show that the integral on the r.h.s. of (7.4) is conditionally convergent in the forceless case \( \nabla H(a) = 0 \). Since the integrand has singularities at the points \( a_1, \ldots, a_K \), it suffices to show that the integrals over the discs, \( D(a_k, \varepsilon) \), centered at \( a_k \) and of a radius \( \varepsilon > 0 \), converge. Consider the integral over the disc \( D(a_k, \varepsilon) \). Let

\[ \varphi(k)(x) = \sum_{j \neq k} \varphi_j(x) . \quad (7.8) \]

Since the function \( \varphi(k)(x) \) is harmonic in \( D(a_k, \varepsilon) \), it has an expansion around the point \( a_k \) of the form

\[ \varphi(k)(x) = \sum_{m=0}^{\infty} c_m r_k^m \cos m(\theta_k - \theta^{(m)}) , \quad (7.9) \]

where \( r_k \) and \( \theta_k \) are the polar coordinates of \( x_k = x - a_k \) and \( c_m \) and \( \theta^{(m)} \) are some constants.

In the forceless case,

\[ \nabla \varphi(k)(a_k) = -\frac{1}{2\pi n_k} J \nabla_{a_k} H(a) = 0 \quad (7.10) \]

and therefore

\[ \nabla \varphi(k)(x) = c_k (x_k \cos 2\theta_k - x_k^1 \sin 2\theta_k) + O \left( \frac{r_k^2}{d_k^2} \right) , \quad (7.11) \]
where \( c_k = O(1/d_{a_k}^2) \) is a constant, \( r_k = |x_k| \) and \( x^\perp = (-x_2, x_1) \). Now, writing

\[
\int_{D(a_k, \varepsilon)} \left( |\nabla \varphi|^4 - |\nabla \varphi_k|^4 \right) = \int_{D(a_k, \varepsilon)} \left( 2|\nabla \varphi_k|^2 \alpha_k + \alpha_k^2 \right), \tag{7.12}
\]

where

\[
\alpha_k := 2\nabla \varphi_k : \nabla \varphi(k) + |\nabla \varphi(k)|^2 \tag{7.13}
\]

and using (7.11), we see that the singular part of the integral above is

\[
4 \int_{D(a_k, \varepsilon)} |\nabla \varphi_k|^2 \nabla \varphi_k : \nabla \varphi(k) =
\]

\[
= 4 \int_{D(a_k, \varepsilon)} \frac{n_k^2}{r_k^2} (-c_k \sin 2\theta_k + O(r_k)) = \int_{D(a_k, \varepsilon)} O\left( \frac{1}{r_k} \right) < \infty . \tag{7.14}
\]

Thus the integral on the r.h.s. of (7.4) is conditionally convergent, in the sense that it is well defined as a limit of the similar integrals with small discs around the points \( a_1, \ldots, a_K \) excised, as the radii of those discs tend to 0.

Now we proceed to establishing estimate (7.6). We begin with proving estimate (7.1) with remainder (7.2). Let \( \psi_i(x) = \psi^{(n_i)}(x_i) \), where \( x_i = x - a_i \), and let \( f_i \equiv |\psi_i| \). Consider a class of functions \( \psi \) of the form \( \psi = f e^{i\varphi_0} \) with a function \( f \) satisfying

\[
f = f_i \quad \text{if} \quad r_i \ll d_a , \quad \forall i \tag{7.15}
\]

where \( n = 2 \) if \( \nabla H(a) = 0 \) and \( n = 1 \) otherwise and \( r_i = |x - a_i| \), and

\[
f = 1 + O\left( \frac{1}{d(x, a)^2} \right) \quad \text{if} \quad d(x, a) \gg 1 , \tag{7.16}
\]

where

\[
d(x, a) = \min_j |x - a_j| ,
\]

with the corresponding estimates of their first derivatives.
We construct a function satisfying (7.15) and (7.16). Let \( D(z, \rho) \) denote the disc of radius \( \rho \) centered at a point \( z \). Let \( \{\chi_j\}_1^K \) be a smooth partition of unity, i.e. \( \sum_{l=1}^{K} \chi_j = 1 \), having the following properties,

\[
D(a_j, \frac{1}{3} d_a) \subset \text{supp} \chi_j \quad \forall j
\]

and

\[
\nabla^n \chi_j = O\left(d_a^{-n}\right) , n = 0, 1, 2 .
\]

Then the following function satisfies (7.15) and (7.16): \( f = \sum f_j \chi_j \). Indeed, (7.15) is obvious, while (7.16) follows from the relation

\[
f_j = 1 + O(r_j^{-2}) \quad \text{(7.17)}
\]

We prove the following

**Lemma 7.2.** Assume \( \psi \) satisfies (7.15)–(7.16). Then

\[
\mathcal{E}_{\text{ren}}(\psi) = E_{\text{ren}}^{(0)} + \text{Rem} + O\left(\frac{1}{R^2}\right) ,
\]

where, recall, \( E_{\text{R}}^{(0)} \) is given in Theorem 7.1 and Rem is given by (7.2).

**Proof.** Let \( D_j = D(a_j, r_0) \), the disc with the center at \( a_j \) and of the radius \( r_0 = \frac{1}{3} d_a \). We decompose the energy functional as

\[
\mathcal{E}_{\text{ren}}(\psi) = \sum_j \int_{D_j} e(\psi) + \int_{(\cup D_j)^c} e(\psi) ,
\]

where \( D^c := \mathbb{R}^2 \setminus D \) and \( e(\psi) \) is the energy density,

\[
e(\psi) = \frac{1}{2}|\nabla \psi|^2 + \frac{1}{4}(|\psi|^2 - 1)^2 .
\]

Let \( e_1(\varphi) = \frac{1}{2}|\nabla \varphi|^2 \) and \( \langle f(\psi) \rangle = f(\psi) - \sum_k f(\psi_k) \). Eqn (4.6) implies

\[
\int_{(\cup D_k)^c} e(\psi) = \int_{(\cup D_k)^c} e_1(\varphi_0) + \int_{(\cup D_k)^c} O\left(d(x, a)^{-4}\right) .
\]

20
Next, the estimates (7.17) and

$$\nabla |\psi_i| = O(r_j^{-3})$$  \hspace{1cm} (7.22)

give

$$\int_{(\cup D_k)^c} e(\psi_i) = \int_{(\cup D_k)^c} e_1(\varphi_i) + O(r_0^{-2}) .$$  \hspace{1cm} (7.23)

This together with Eqn (7.21) yields

$$\int_{(\cup D_k)^c} \left( e(\psi) - \frac{1}{2} \sum_{i \neq j} \nabla \varphi_i \nabla \varphi_j \right) = O(r_0^{-2}) .$$  \hspace{1cm} (7.24)

Next, in the region $D_i$ we have $\psi = e^{i\varphi_0} f_i$, where, recall, $f_i \equiv |\psi_i|$. Expansion (7.9) implies that

$$\int_{D_i} \nabla \varphi_i \cdot \nabla \varphi^{(i)} = 0 .$$ \hspace{1cm} (7.25)

Using this relation we obtain

$$\int_{D_i} e(\psi) = \int_{D_i} e(\psi_i) + \int_{D_i} e_1(\varphi^{(i)}) + R ,$$

where

$$R = \int_{D_i} (f_i^2 - 1) \alpha_i .$$

Expanding

$$\nabla \varphi^{(i)} = \nabla \varphi^{(i)}(a_i) + O\left(\frac{r_i}{d_2^2}\right)$$ \hspace{1cm} (7.26)

and using that $|\nabla \varphi^{(i)}(x)|^2 = O(\bar{d}(x, \bar{a})^{-2})$, $\nabla \varphi_i(x) = O(r_i^{-1})$ and $\int_{D_i} (1 - f_i^2) \nabla \varphi_i = 0$, we obtain that

$$R = O\left(\frac{\ln r_0}{d_2^2}\right) .$$

21
In the forceless case we can improve this estimate using relation (7.9) again to show that, as in (7.14),

$$
\int_{D_i} (f_i^2 - 1) \nabla \varphi_i \cdot \nabla \varphi_{(i)}
$$

$$
= \int_{D_i} (f_i^2 - 1) \left(-c_t \sin 2\theta_i + O \left( \frac{r_i}{d_+^2} \right) \right)
$$

$$
= \int_{D_i} (f_i^2 - 1) O \left( \frac{r_i}{d_+^2} \right) = O \left( \frac{r_0}{d_+^2} \right)
$$

This gives

$$
R = O \left( \frac{r_0}{d_+^2} \right) \quad \text{if} \quad \nabla \varphi_i (a_i) = 0 .
$$

Finally, we observe that due to (7.15)

$$
\frac{1}{2} \int_{D_k} |\nabla \varphi(k)|^2 = \sum_{j \neq k} \int_{D_k} \left( e_1 (\psi_j) + I \right)
$$

$$
= \sum_{j \neq k} \int_{D_k} \left( e(\psi_j) + I \right) + O(r_0^{-2}) ,
$$

where $I := \frac{1}{2} \sum_{i \neq j} \nabla \varphi_i \cdot \nabla \varphi_j$

Collecting the estimates above, we arrive at

$$
\int_{D_k} \langle e(\psi) \rangle = \int_{D_k} I + O \left( \ln \frac{r_0}{d_+} \right) + O \left( \frac{1}{r_0^2} \right) , \quad (7.27)
$$

which together with (7.19) and (7.24) yields

$$
\mathcal{E}_{\text{ren}}(\psi) = E + \text{Rem} \quad (7.28)
$$

where Rem is given in (7.2) and $E = \int (g - \frac{n^2}{r^2} \chi)$ with $g = \sum_j e(\psi_j) + I$ and $n = \text{deg} \psi$.

Denote by $D_R$ the disc of the radius $R$ centered at the origin. Now, by the definition of the cut-off function $\chi \ (\chi \geq 0 , \ \chi = 1 \text{ for } |x| \geq R)$ we have

$$
E \leq \int_{D_R} g + \int_{D_R^c} \left( g - \frac{n^2}{2r^2} \right) . \quad (7.29)
$$
First we compute the first integral on the r.h.s.:

By the definition $E_{n,R}$ and since $a_i \ll R$ we have

$$\int_{D_R} e(\psi_i) = \int_{D_{R+a_i}} e(\psi^{(ni)}) = E_{n_i,R} + O\left(\frac{1}{R^2}\right). \quad (7.30)$$

Now we show that

$$I_{D_R} \equiv \frac{1}{2} \sum_{i \neq j} \int_{D_R} \nabla \varphi_i \nabla \varphi_j = - \sum_{i \neq j} \pi n_i n_j \ln \left(\frac{|a_{ij}|}{R}\right). \quad (7.31)$$

We compute

$$\int_{D_R} \nabla \varphi_i \nabla \varphi_j = n_i n_j \int_0^{2\pi} \int_0^R \frac{r - a \cos \theta}{r^2 + a^2 - 2ar \cos \theta} \, dr \, d\theta, \quad (7.32)$$

where $a = |a_{ij}|$. Furthermore, changing the variable of integration as $\theta \to z = e^{i\theta}$ and computing the residue, we find

$$\int_0^{2\pi} \frac{r - a \cos \theta}{r^2 + a^2 - 2ar \cos \theta} \, d\theta = \frac{\pi}{r} - \frac{r^2 - a^2}{2iar^2} \oint_{|z|=1} \frac{dz}{(z - \frac{r}{a})(z - \frac{a}{r})} = \frac{\pi}{r} + \frac{\pi}{r} \frac{r^2 - a^2}{|r^2 - a^2|} = \frac{2\pi}{r} \begin{cases} 1 & \text{if } r > a \\ 0 & \text{if } r < a \end{cases}.$$

The last two equations yield (7.24). Observe also that up to a multiplicative constant expression (7.24) can be found from the symmetry considerations: the invariance of the integral on the l.h.s. under translations ($a_i \to a_i + h$ and $a_j \to a_j + h \forall h \in \mathbb{R}^2$) and rotations ($a_i \to ga_i$ and $a_j \to ga_j \forall g \in O(2)$) imply that it depends only on $|a_{ij}|$. Its scaling properties under the dilations ($a_i \to \lambda a_i$ and $a_j \to \lambda a_j \forall \lambda \in \mathbb{R}$) imply that it is a multiple of $\ln \left(\frac{|a_{ij}|}{R}\right)$.

Eqns (7.30) and (7.31) imply

$$\int_{D_R} g = \sum_{n_i} E_{n_i,R} + H(a/R) + O(1/R^2). \quad (7.33)$$
Next we estimate the second integral on the r.h.s. of (7.29). By Eqn (7.17) and (7.22) we have
\[
g = \frac{1}{2} |\nabla \varphi_0|^2 + O(d(x,\mathbb{a})^{-4}) .
\]
Furthermore, expanding the terms \(\nabla \theta(x - a_j)\) in \(\nabla \varphi_0(x) = \sum n_j \nabla \theta(x - a_j)\) around the point \(x\) we obtain
\[
\nabla \varphi_0(x) = n \nabla \theta(x) - \theta''(x) \sum n_j a_j + O\left(\frac{\sum n_j a_j^2}{d(x,\mathbb{a})^3}\right) ,
\]
(7.34)
where \(\theta''(x)\) is the Hessian of \(\theta(x)\). Choosing the origin so that \(\sum n_j a_j = 0\) eliminates the second term on the r.h.s. (Otherwise we could have used that by an explicit computation we have
\[
\theta''(x) \nabla \theta(x) = -\frac{x}{r^4} ,
\]
the integral of which over the exterior of the ball \(B(0,R)\) vanishes.) Hence
\[
\int_{D^c_R} \left( g - \frac{n^2}{2r^2} \right) = \int_{D^c_R} O\left(\frac{\sum n_j a_j^2}{d(x,\mathbb{a})^4}\right) = O\left(\frac{\sum n_j a_j^2}{R^2}\right) ,
\]
(7.35)
Estimates (7.28), (7.29), (7.33) and (7.35) imply (7.15) with Rem given in (7.2). \(\square\)

**Remark 7.3.** The statement of Lemma 7.2 remains true for a wider class of functions defined by replacing (7.15) by the following condition
\[
f = f_i + O\left(\frac{1}{r_i \cdot d^m_{\mathbb{a}}} \right) \quad \text{and} \quad \int_0^{2\pi} \text{Re}(e^{-i\varphi_0} \psi - f_i) d\theta = O\left(\frac{1}{d_{\mathbb{a}}^{n+1}}\right) ,
\]
(7.36)
if \(|x - a_i| \ll d_\mathbb{a}|\),
with the corresponding estimates of their first derivatives, where \(n = 2\) if \(\nabla H(\mathbb{a}) = 0\) and \(n = 1\) otherwise.
To prove this we write $\psi$ in the region $D_i$ as $\psi = e^{i\varphi_0}(f_i + \xi)$, where $f_i \equiv |\psi_i|$. Using relation (7.25) and using that

$$
\int_{D_j} f_j \nabla \varphi_j \cdot \nabla \text{Im} \xi = n_j \int_{D_j} f_j \frac{\partial}{\partial \theta} \text{Im} \xi = 0 , \quad (7.37)
$$

we obtain

$$
\int_{D_i} e(\psi) = \int_{D_i} e(\psi_i) + \int_{D_i} e_1(\varphi(i)) + R + R' , \quad (7.38)
$$

where $R$ is given above and

$$
R' = \int_{D_i} \left\{ (|\nabla \varphi_0|^2 + f_i^2 - 1)f_i \text{Re} \xi + f_i^2(\text{Re} \xi)^2 \\
+ \frac{1}{2} |\nabla \varphi_0|^2 |\xi|^2 + \frac{1}{2} |\nabla \xi|^2 + 2 \nabla f_i \cdot \nabla \text{Re} \xi + f_i \nabla \varphi_0 \cdot \nabla \text{Im} \xi \\
+ \text{Im}(\xi \nabla \varphi_0 \cdot \nabla \xi) + \frac{1}{2} (f_i^2 - 1 + 2f_i \text{Re} \xi)|\xi|^2 + \frac{1}{4} |\xi|^4 \right\} .
$$

Using that, due to (7.36), $\xi = O\left(\frac{1}{r_i d_a} \right)$ and $\int_0^{2\pi} \text{Re} \xi \, d\theta = O\left(\frac{1}{d_a^2} \right)$ in $D_j$ and using that $|\nabla \varphi_i|^2 + f_i^2 - 1 = O(r_i^{-4})$, we find

$$
R' = O\left(\frac{\ln r_0}{d_a^2} \right) . \quad (7.40)
$$

Now we proceed to proving estimate (7.1) with $R$ given by (7.3). First we describe a class of test functions for which we prove this estimate: $\psi = e^{i\varphi_0} f$ with

$$
f = \begin{cases} 
\frac{f_j}{1 - \frac{1}{2} |\nabla \varphi_0|^2 + O(d(x, a)^{-4})} & \text{in } D(a_j, \frac{1}{2} d_a) \quad \forall j \\
\frac{1}{2} f_j^{-1} \alpha_j \eta_j & \text{in } D(a_j, \frac{1}{3} d_a) \\
1 - \frac{1}{2 |\nabla \varphi_0|^2 + O(d(x, a)^{-4})} & \text{in } \left( \bigcup_j D(a_j, \frac{1}{4} d_a) \right)^c 
\end{cases} \quad (7.41)
$$

where we used definition (7.13) and where $\eta_j$ are smooth cut-off functions depending only on $r_j = |x_j|$ (i.e. radially symmetric in the $x_j$-variables) satisfying

$$
D(a_j, \frac{1}{2} d_a) \setminus D(a_j, 2d_a) \subset \text{supp} \eta_j \subset D(a_j, \frac{1}{2} d_a) \setminus D(a_j, d_a) \quad (7.43)
$$

and

$$
\nabla^n \eta_j = O\left(d_a^{-\gamma n} \right) , \quad n = 0, 1, 2 , \quad (7.44)
$$
for $\gamma = \frac{1}{3}$ (not optimal). (The $f_j^{-1}$'s in (7.41) play no important role and are chosen purely with a view of simplifying some expressions below.)

The following function satisfies (7.41) and (7.42)

$$f = \sum f_j x_j - \sum \frac{1}{2} f_j^{-1} \alpha_j \eta_j .$$

(7.45)

To prove this we use the expansion

$$f_j = 1 - \frac{1}{2} |\nabla \varphi_j|^2 + O(r_j^{-4})$$

(7.46)

and the estimate

$$\alpha_j = O(d_j^{-2}) \text{ in } D(a_j, d_j) ,$$

(7.47)

which is shown by expanding the function $\nabla \varphi_{(j)}(x)$ around $a_j$ and using that $\nabla \varphi_{(j)}(a_j) = -\frac{1}{2\pi \eta_j} \nabla a_j H(a) = 0$ and that $\nabla \varphi_j(x) = O(r_j^{-1})$.

Our next task is to prove the following

**Lemma 7.4.** Let $g$ be forceless in the sense that $\nabla H(a) = 0$. Then estimate (7.7) with (7.3) holds for any function $\psi$ satisfying (7.21)–(7.22).

**Proof.** The proof follows the lines of the proof of Lemma 7.2 but with some subtle modifications which we elaborate upon now.

First of all instead of $e_1(\psi) = \frac{1}{2} |\nabla \varphi|^2$ used in the proof of Lemma 7.2 we use the density

$$e_2(\varphi) = \frac{1}{2} |\nabla \varphi|^2 - \frac{1}{4} |\nabla \varphi|^4 ,$$

(7.48)

which is a better approximation to the density $e(\psi)$, and instead of (7.17) we use (7.27). In particular we have

$$e(\psi_j) = e_2(\varphi_j) + O(r_j^{-6}) .$$

(7.49)
Denote $f_j := 1 - f_j^2 - |\nabla \varphi_j|^2$. For any $k$ and for $u_k = e^{i\varphi_0}(f_k + \xi)$, where $\xi$ is a real function, we have the following identity

$$<e(u_k)> = \frac{1}{2} \sum_{i \neq j} \nabla \varphi_i \cdot \nabla \varphi_j - A(\varphi) + B_k(\xi) + R_k,$$

(7.50)

where

$$B_k(\xi) := -\frac{1}{2} g_k(\alpha_k + 2 f_k \xi) + \frac{1}{4} \alpha_k^2 + \alpha_k f_k \xi + f_k^2 \xi_k^2$$

(7.51)

and

$$R = \sum_{j \neq k} \left( e_2(\varphi_j) - e(\psi_j) \right) - \frac{1}{2} (g_k - \alpha_k) \xi^2 + f_k \xi_k + \frac{1}{4} \xi_k^4$$

$$+ \frac{1}{2} (2 \nabla f_k \cdot \nabla \xi + |\nabla \xi|^2)$$

(7.52)

Now we take $\xi = -\frac{1}{2} f_k^{-1} \alpha_k \eta_k$. Then

$$e(\psi) = e(u_k) \text{ on } D(a_k, \frac{1}{3} d_a).$$

(7.53)

Due to (7.28) and the corresponding estimate for the derivatives of $\alpha_j$ and due to (7.25), (7.27) and (7.29) we have

$$R_k = O(d_a^{-4\gamma - 2})$$

(7.54)

Note now that the form of (7.21) is chosen so that

$$B_k(\xi) = 0 \text{ on } D(a_k, \frac{1}{2} d_a) \setminus D(a_k, d_a^\gamma) \subset \{ \eta_k = 1 \}.$$

Now we estimate $B_k(\xi)$ on the entire disc $D(a_k, \frac{1}{3} d_a)$. Expanding the function $\nabla \varphi(\kappa)(x)$ around the point $a_k$ and using that $\nabla \varphi(\kappa)(a_k) = -\frac{1}{2\pi \eta_k} J \nabla a_k H(a) = 0$, we find

$$\alpha_k(x) = 2 \nabla \varphi_k(x) \cdot \varphi''(\kappa)(a_k)x_k + O(r_k d_a^{-3}),$$

(7.55)

where, recall, $x_k = -a_k$, and $\varphi''$ is the Hessian (the matrix of second derivatives) of a function $\varphi$. Using this expression in estimating $B_k(\xi)$ we find

$$B_k(\xi) = -g_k \nabla \varphi_k(x) \cdot \varphi''(\kappa)(a_k)x_k \bar{\eta}_k + O(r^{-3} d_a^{-3} + d_a^{-4}) \bar{\eta}_k \text{ on } D(a_k, \frac{1}{3} d_a),$$

(7.56)
where \( \bar{\eta}_k = 1 - \eta_k \). The first term on the r.h.s. of this expression is singular at \( x_k = x - a_k = 0 \), but the integral of it is conditionally convergent and equals 0. Indeed, since the function \( \varphi(k)(x) \) is harmonic in \( D(a_k, \frac{1}{3}d_a) \) we have that (cf (7.11))

\[
\varphi''(k)(a_k)x_k = c(x_k \cos 2\theta_k - x_k^+ \sin 2\theta_k),
\]

where \( c = O\left(d_{a_k}^{-2}\right) \), \( x^+ = (-x_2, x_1) \) and \( \theta_k \) is the polar angle of \( x_k \) (see Eqn (7.9)). Since \( g_k \) and \( \bar{\eta}_k \) depend only on \( r_k \) (we write \( (g_k \bar{\eta}_k)(r_k) \) for \( g_k(x)\bar{\eta}_k(x) \)), we have

\[
\int (g_k \bar{\eta}_k)(r_k) \nabla \varphi_k(x) \varphi''(k)(a_k)x_k = -c \int (g_k \bar{\eta}_k)(r_k) \sin 2\theta_k = 0
\]

(Strictly speaking we have first to excise a small disc around \( x_k = 0 \) and then take the radius of this disc to zero).

Eqns (7.32), (7.33), (7.35) and (7.37) imply that

\[
\int_{D \left( a_k, \frac{1}{3}d_a \right)} < e(\psi) > = \int_{D \left( a_k, \frac{1}{3}d_a \right)} \left( \frac{1}{2} \sum_{i \neq j} \nabla \varphi_i \cdot \nabla \varphi_j - A(\varphi) \right) + O \left( d_{a_k}^{-3} + d_{a_k}^{-2-4\gamma} + d_{a_k}^{-4+2\gamma} \right).
\]

Finally, we derive the estimate

\[
< e(\psi) > = \frac{1}{2} \sum_{i \neq j} \nabla \varphi_i \nabla \varphi_j - A(\varphi) + O \left( d(x, a)^{-6} \right)
\]

on \( \left( \bigcup_k D(a_k, \frac{1}{3}d_a) \right)^c \). Indeed, Eqn (7.42) implies that

\[
e(\psi) = e_2(\varphi_0) + O \left( d(x, a)^{-6} \right),
\]

which together with (7.49) implies (7.60).

Now, Eqns (7.59) and (7.60) with \( \gamma = 1/3 \) imply

\[
\mathcal{E}_R(\psi) = E - A(a) + O \left( d_{a_k}^{8/3} \right),
\]

28
where the term $E$ is defined after Eqn (7.28) and $A(a) = \int A(\varphi)$. Eqns (7.29), (7.33), (7.35) and (7.61) imply (7.7) with Rem given by (7.3). $\Box$

Lemmas 7.2 and 7.4 and inequality (7.6) imply Theorem 7.1. $\Box$

Acknowledgement. The authors are grateful to A. Knauf and L. Sadun for a stimulating discussion. In fact, it was A. Knauf who suggested that there might be static multivortex configurations.

Appendix 1. Computation of $c(n)$

In this appendix we compute the constants $c(n)$ in expression (3.5) for the self-energy, $E_{n,R}$, of the $n$-vortex (see Eqn (3.6)). To this end we derive a convenient formula for $E_{n,R}$. Multiplying Eqn (3.2) by $r^2 f'_n(r)$, where $f'(r) = \frac{\partial f(r)}{\partial r}$, integrating the result over $r$, observing that the first two integrands are full derivatives and integrating the last term by parts, we obtain the quantization relation (see [BMR])

$$\int_0^\infty (1 - f_n^2)^2 r \, dr = n^2 .$$

This equation together with Eqn (3.3) yields an expression for $E_{n,R}$:

$$E_{n,R} = -\frac{1}{2} \pi n^2 + \pi \int_0^\infty (1 - f_n^2 - \frac{n^2}{r^2} \chi) r \, dr .$$

However we prefer to use a different representation of $E_{n,R}$ which is obtained from above if we write $1 - f_n^2 = (1 - f_n^2)f_n^2 + (1 - f_n^2)^2$ and use the quantization formula above again:

$$E_{n,R} = -\frac{1}{2} \pi n^2 + \pi \int_0^\infty [(1 - f_n^2)f_n^2 - \frac{n^2}{r^2} \chi] r \, dr .$$

(A1.1)

First of all in order to avoid a numerical evaluation of the integral in (A1.1) over an infinite range, we use for large $r$ an expansion of $f_n(r)$ in $\frac{1}{r}$. However, $f_n(r)$ is not
analytic at \( r = \infty \), it has an essential singularity at this point. Hence the resulting series is asymptotic. We truncate this series at the order \( O \left( \frac{1}{r^6} \right) \). To compensate for this truncation we add to the resulting polynomial in \( \frac{1}{r} \) a multiple of the decaying solution \( e^{-\sqrt{2r}/r} \) of the linearization of Eqn (3.2) around 1. We should linearize Eqn (3.2) around the resulting polynomial, but the powers of \( \frac{1}{r^2} \) lead to similar powers multiplying \( e^{-\sqrt{2r}/r} \), thus it suffices to linearize around 1. The result is

\[
f_n(r) = \left\{ 1 - \frac{n^2}{2r^2} - \frac{n^2(1 + n^2/8)}{r^4} - \frac{1}{r^6} \left( \frac{n^4}{2} \right. \\
+ \frac{n^2 + 16}{2} \left( n^2 + \frac{n^4}{8} \right) \left. \right) - \cdots \right\} - c \frac{e^{-\sqrt{2r}}}{\sqrt{r}} (1 + \cdots),
\]

where \( c \) is a constant to be determined by a matching procedure. Plugging this expression into Eqn (A1.1), we obtain

\[
E_{n,R} - \pi n^2 \ln R = \frac{\pi n^2}{2} + \pi \int_0^{r_0} f_n^2(1 - f_n^2) r dr \\
- \pi n^2 \left( \ln r_0 + \frac{n^2 - 2}{2r_0^2} + \frac{n^2 - 16}{4r_0^4} \right) + O(r_0^{-6})
\]

for any \( r_0 > 0 \). We pick \( 6 \leq r_0 \leq 10 \). This relation together with Eqn (3.5) implies that

\[
\frac{1}{\pi} c(n) = \frac{n^2}{2} + \int_0^{r_0} f_n^2(1 - f_n^2) r dr \\
- n^2 \left( \ln \frac{r_0}{n} + \frac{n^2 - 2}{2r_0^2} + \frac{n^2 - 16}{4r_0^4} \right) + O(r_0^{-6}).
\]

For a numerical solution of Eqn (3.2) we take the interval \((0.3, r_0)\). Since Eqn (3.2) linearized around the function 1 has the solutions

\[
\frac{1}{\sqrt{r}} e^{\pm \sqrt{2r}},
\]

one should do the numerical iteration procedure starting from the upper limit, \( r_0 \). In this way the dangerous, exponentially growing solution would not effect our procedure.
In the range $0 < r \leq 0.3$ we use the fact that, as Eqn (3.2) shows, the function $f_n(r)$ is analytic in a disc $|r| < O(1)$, so it can be presented by a convergent series:

$$f_n(r) = \alpha r^n \left\{ 1 - \frac{r^2}{4(n+1)} + \frac{r^4}{8(n+2)} \left( \frac{1}{4(n+1)} + \alpha^2 \delta_{n,1} \right) + \frac{r^6}{12(n+3)} \left[ \alpha^2 \left( \delta_{n,2} - \frac{3}{4(n+1)} \delta_{n,1} \right) - \frac{1}{8(n+2)} \left( \frac{1}{4(n+1)} + \alpha^2 \delta_{n,1} \right) \right] + \ldots \right\} \quad (A1.6)$$

for some number $\alpha > 0$. Here $\delta_{n,k}$ is the Kronecker symbol, $\delta_{n,k} = 1$ for $n = k$ and $= 0$ for $n \neq k$. (We expect that the pole closest to the origin lies on the imaginary axis.)

To finish off the computation of $c(n)$ we have to find the value of the parameters $\alpha$ and $c$. This is done by matching the solution (A1.2) for small $r$ with that, Eqn (A1.6), for large $r$. Specifically, using Eqn (A1.2), we compute $f_n(r_0)$ and $f'_n(r_0)$ for various values of the parameter $c$. Using these values as initial conditions, we integrate Eqn (3.2) backward to $r = 0.3$, which yields $f_{\text{right}}(0.3)$ and $f'_{\text{right}}(0.3)$. On the other hand using Eqn (A1.6), we compute $f_{\text{left}}(0.3)$ and $f'_{\text{left}}(0.3)$ for various values of the parameter $\alpha$. Now we match $f_{\text{right}}(0.3)$ and $f'_{\text{right}}(0.3)$ with $f_{\text{left}}(0.3)$ and $f'_{\text{left}}(0.3)$ by minimizing $[(f_{\text{right}}(0.3) - f_{\text{left}}(0.3))^2 + (f'_{\text{right}}(0.3) - f'_{\text{left}}(0.3))^2]^{1/2}$. This yields the values of the parameters $c$ and $\alpha$. After this we compute $c(n)$, using formulae (A1.4) and (A1.6).

**Appendix 2. Large $n$ asymptotics of the vortex (self) energy**

In this appendix we find the large $n$ asymptotics of the constant $c(n)$ in expression (3.6) for the (self) energy of the $n$-vortex. To this end we use the following large $n$ asymptotics for the function $f_n(r)$ defined in (3.2):

$$f_n(r) = \begin{cases} \sqrt{1 - \frac{n^2}{r^2}} & \text{if } r - n \gg \left( \frac{n}{2} \right)^\frac{1}{3}, \\
\left( \frac{2}{n} \right)^\frac{1}{3} g(z) & \text{if } |r - n| \ll n \end{cases} \quad (A2.1)$$
where the variable \( z \) is defined by the relation

\[
r = n + \left( \frac{n}{2} \right)^{\frac{1}{5}} z \tag{A2.2}
\]

and the function \( g(z) \) is a solution to the equation

\[
g'' + zg - g^3 = 0 . \tag{A2.3}
\]

The function \( g(z) \) has the following asymptotics:

\[
g(z) = z^{\frac{1}{2}} \quad \text{if} \quad z \gg 1 \tag{A2.4}
\]

\[
= \text{const} \, \phi(z) \quad \text{if} \quad z \ll -1 ,
\]

where \( \phi(z) \) is the Eiry function. In particular, we have

\[
g(z) = \frac{0.39}{(-z)^{\frac{1}{3}}} e^{-\frac{2}{3}(-z)^{3/2}} \quad \text{for} \quad z \ll -1 . \tag{A2.5}
\]

Plugging expression (A2.1)-(A2.2) into Eqn (A1.1) and using (A2.4) and (A2.5), we find that

\[
c(n) = an^{\frac{2}{3}} \pi + c + O(n^{-\frac{2}{3}}) , \tag{A2.6}
\]

where \( c \) is some constant and

\[
\alpha = 2^{\frac{1}{3}} \int_{-\infty}^{\infty} (g^2(z) - z\theta(z)) dz , \tag{A2.7}
\]

\( \theta(z) = 1 \) for \( z \geq 0 \) and \( = 0 \) for \( z < 0 \). Multiplying Eqn (A2.3) by \( g'(z) \) and taking the integral of the result, we find that \( \alpha = 0 \) and therefore

\[
c(n) = c + O(n^{-\frac{2}{3}}) \tag{A2.8}
\]

as \( n \to \infty \). A rough numerical computation yields the following value for the constant \( c \):

\[
c \approx 0.7 \pi . \tag{A2.9}
\]
Appendix 3. Computation of correlation coefficients

In this appendix we compute the correlation function

\[ A = A(a) = \frac{1}{4} \int \left[ |\nabla \varphi_0|^4 - \sum_j |\nabla \varphi_j|^4 \right] \]  \hspace{1cm} (A3.1)

with

\[ \varphi_0 = \sum_j \varphi_j \quad \text{and} \quad \varphi_j(x) = n_j \theta(x - a_j), \]  \hspace{1cm} (A3.2)

\[ \theta(x) = \text{the polar angle of } x \in \mathbb{R}^2. \]  \hspace{1cm} (A3.3)

(see Eqn (4.4)) for configurations of \( K = N + 1 \) vortices with \( N \) vortices of vorticity \( m \) lying in the circle of radius \( a \) and one vortex of vorticity \( -k \), at the center of this circle, s.t. \( \nabla H(a) = 0 \).

Write \( a = a \cdot b \) where \( b \) is a fixed configuration with \( N \) vortices on a unit circle and one, in the center. Changing the variable of integration in (A3.4) as \( x = ay \), we find

\[ A(a) = Ca^{-2} \]  \hspace{1cm} (A3.4)

where \( C \) depends on \( b \) only. Our task now is to find the sign of \( C \) for the configurations of interest. We denote \( A = A(a) \).

1. \( N = 2, m = 2 \) and \( k = 1 \). Here there are two double vortices on the circle and one single vortex of opposite vorticity at the center (see Fig 1). Below we shall use the dimensionless variable

\[ \rho = \frac{|x|}{a}. \]  \hspace{1cm} (A3.5)

For the configuration under consideration we have

\[ A = \frac{1}{4a^2} \int_0^\infty \rho d\rho \int_0^{2\pi} d\theta \left\{ 48 \frac{\cos(2\theta)}{\alpha} - \frac{16 \cos(2\theta)}{\alpha \rho^2} + \frac{64 \cos^2(2\theta)}{\alpha^2} - \frac{64}{\alpha^2} (1 + 2\rho^2 + 2\rho^2 \cos(2\theta)) \right\}, \]  \hspace{1cm} (A3.6)
where
\[
\alpha = \rho^4 + 1 + 2\rho^2 \cos(2\theta) .
\] (A3.7)

(In general, for \(a_j, j = 1, \ldots, N\), distributed equidistantly on the circle of radius \(a\), \(\alpha = \prod_{j=1}^{N} (x - a_j)^2 / a^{2N}\).) First we take an integral over \(\theta\). To this end we change the variable of integration as \(\theta \to z = \exp(2i\theta)\), i.e. we write the internal integral in (A3.8) as an integral over a unit circle. A simple calculation gives
\[
\int_{0}^{2\pi} \frac{d\theta}{\alpha^2} = \frac{2\pi(1 + \rho^4)}{|1 - \rho^4|^3} , \quad \int_{0}^{2\pi} \frac{d\theta}{\alpha^2} \cos(2\theta) = -\frac{4\pi \rho^2}{|1 - \rho^4|^3} ,
\] (A3.8)
\[
\int_{0}^{2\pi} \frac{d\theta}{\alpha} = \frac{2\pi \rho^2}{|1 - \rho^4|} , \quad \int_{0}^{2\pi} \frac{d\theta}{\alpha} \cos(2\theta) = -\frac{2\pi}{|1 - \rho^4|} \min \left\{ \rho^2, \frac{1}{\rho^2} \right\} ,
\] (A3.9)
\[
\int_{0}^{2\pi} \frac{d\theta}{\alpha^2} \cos^2(2\theta) = \frac{\pi}{|1 - \rho^4|^3} \left\{ \frac{1 + 4\rho^4 - \rho^8}{\rho^4} \right\}
\quad \text{for } \rho < 1 \quad \text{and} \quad \left\{ \frac{(\rho^6 + 4\rho^4 - 1)/\rho^4}{\rho^8} \right\}
\quad \text{for } \rho > 1 .
\] (A3.10)

Inserting expressions (A3.7)–(A3.10) into Eqn (A3.7), we obtain
\[
A = \frac{4\pi}{a^2} \left\{ 2 \int_{0}^{1} dx \frac{1 - x}{(1 + x)^3} + \int_{1}^{\infty} dx \frac{3x + 1 + \frac{3}{x} + \frac{1}{x^2}}{(1 + x)^3} \right\} .
\]

This gives
\[
A = \frac{8\pi}{a^2} .
\] (A3.11)

Hence in the configuration under consideration the energy \(E_R(\rho)\) is given by
\[
\frac{1}{\pi} E_R(\rho) - 9 \ln R = -9.64 - \frac{8}{a^2} + O \left( \frac{\ln a}{a^4} \right) .
\] (A3.12)

2. \(N = 3, m = 1\) and \(k = 1\). Similarly to Eqn (A3.8) we obtain
\[
A = \frac{1}{4a^2} \int_{0}^{\infty} d\rho \int_{0}^{2\pi} d\theta \left\{ \frac{6}{\alpha} (1 + 2\rho^2) - \frac{12 \sin(3\theta)}{\rho \alpha} - \frac{9(1 + \rho^2)(1 + \rho^2 + 2\rho^4) + 36\rho^2 \sin^2(3\theta)}{\alpha^2} - \frac{36\rho^5 \sin(3\theta)}{\alpha^2} \right\} ,
\] (A3.13)
where $\alpha = \rho^6 + 1 + 2\rho^3 \sin(3\theta)$. The integrals in Eqn (A.13) can be taken explicitly. To do this we set $z = \exp(3i\theta)$.

$$
\int_0^{2\pi} \frac{d\theta}{\alpha} = \frac{2\pi}{|1 - \rho^6|}, \quad \int_0^{2\pi} \frac{d\theta}{\alpha^2} = \frac{2\pi(1 + \rho^6)}{|1 - \rho^6|^3},
$$

and

$$
\int_0^{2\pi} \frac{d\theta}{\alpha^2} \sin^2(3\theta) = \frac{\pi}{|1 - \rho^6|^3} \left\{ 1 + 4\rho^6 - \rho^{12} \quad \text{for } \rho < 1 \right. \\
\left. (\rho^{12} + 4\rho^6 - 1)/\rho^6 \quad \text{for } \rho > 1. \right. \tag{A.16}
$$

Inserting expressions (A.14)–(A.16) into Eqn (A.13), we obtain

$$
A = \frac{3\pi}{4a^2} \left\{ \int_0^1 dx \frac{5x + 9x^2 - 1 - 2x^3 - 2x^4}{(1 + x + x^2)^3} \\
+ \int_1^\infty dx \left( \frac{4}{1 + x + x^2} - \frac{9}{(1 + x + x^2)^2} + \frac{10x + 18}{(1 + x + x^2)^3} + \frac{6x + 2}{x^2(1 + x + x^2)^3} \right) \right\}. \tag{A.17}
$$

A simple calculation of integrals in Eqn (A.16) gives explicit answers for $A$:

$$
A = \frac{2\pi}{a^2}. \tag{A.18}
$$

Hence the energy for such configurations is given by

$$
\frac{1}{\pi} E_R(a) - 4 \ln R = -1.792 - \frac{2}{a^2}. \tag{A.19}
$$

3. $N = 4$, $m = 2$ and $k = 3$. Here, there are four double vortices in the corners of a rectangular and a (-3)-vortex in the centre. For this configuration we have

$$
A = \frac{16}{a^2} \int_0^{2\pi} d\theta \int_0^\infty dp \cdot \frac{\rho}{\alpha} \left\{ \frac{4\rho^{12}}{\alpha} + \frac{36\rho^4 \cos^2(4\theta)}{\alpha} + 4.5\rho^4 \\
+ 13.5 \cos(4\theta) + \frac{24\rho^5}{\alpha} \cos(4\theta) - \frac{1}{\alpha} [(\rho^2 + 1)^6 - 2\rho^2(\rho^2 + 1)^2(\rho^4 + 1) + 4\rho^6] \\
- 2\rho^4 \cos(4\theta)(3(\rho^2 + 1)^2 - 2\rho^2)/\alpha \right\}, \tag{A.20}
$$
where

\[ \alpha = \rho^8 + 1 - 2\rho^4 \cos(4\theta) . \]

The change of variables \( 2\theta \to \tilde{\theta} + \frac{\pi}{2}, \rho^8 \to \tilde{\rho}^4 \) reduces the integrals over \( \theta \) in Eqn (A3.20) to the one given in Eqns (A3.8)–(A3.10). As a result we obtain

\[
A = \frac{16\pi}{a^2} \left\{ \int_0^1 dx \left[ \frac{1 - 3x}{1 + x + x^2 + x^3} + \frac{2(5x^5 + 23x^4 + 18x^3 + 6x^2 - 3x - 1)}{(1 + x + x^2 + x^3)^3} \right]
+ \int_1^\infty dx \left( \frac{7.5}{1 + x^2} - \frac{1.5}{x^2(1 + x^2)} - \frac{4(1 + x + x^2)}{x^2(1 + x + x^2 + x^3)} - \frac{2}{(1 + x + x^2 + x^3)^3} \left( x^5 + 11x^4 - 2x^3 - 22x^2 - 31x - 21 - \frac{12}{x} - \frac{4}{x^2} \right) \right) \right\}
\]  

(A3.21)

A direct calculation of the integrals in Eqn (A3.11) gives the following answer

\[
A = \frac{80\pi}{a^2}
\]  

(A3.22)

and therefore the energy of the configuration in question is

\[
\frac{1}{\pi} E_R(a) - 25 \ln R = -40.44 - \frac{80}{a^2}.
\]  

(A3.23)

Note, that for all the configurations under consideration the correlation term, \( A \), is given by

\[
A = \frac{\pi}{4a^2} \cdot M
\]

where \( M \) is an integer, i.e. the quantity given by an integral in \( A \) is quantized. Moreover, the “quantization” takes place separately for the integrals over regions \( r < 1 \) and \( r > 1 \).

We conjecture that this property is general and holds for any forceless configuration.

**Appendix 4. Inequality \( E'_R(0) > 0 \)**

In this appendix we show that \( E_R(a) - E_R(0) > 0 \) for the configuration consisting of \( N \) 1-vortices equidistributed on the circle of radius \( a \) and one \( (-\frac{N-1}{2}) \)-vortex in the center and for \( a \) sufficiently small. We assume that \( N \) is odd but otherwise arbitrary.
For $a = 0$ the configuration in question collapses into a single $\frac{N+1}{2}$-vortex, $\psi_{\frac{N+1}{2}}$, sitting at the origin. Let $L$ be the Hessian of $E_{\text{ren}}(\psi)$ at $\psi = \psi_{\frac{N+1}{2}}$. It was shown in [OS1] that the subspaces

$$\left\{ u_1(r)e^{im\theta} + u_2(r)e^{i(2\frac{N+1}{2} - m)\theta} \mid u_k \in L^2(\mathbb{R}d\theta), \ k = 1, 2 \right\}, \quad (A4.1)$$

$m = \frac{N+1}{2}, \frac{N+1}{2} + 1, \ldots$, which are orthogonal to each other and span the entire Hilbert space $L^2(\mathbb{R}^2)$, are invariant under action of the operator $L$. Moreover, it was shown that $L$ in the sectors with $m \geq 3\frac{N-1}{2} - 1$ is non-negative and 0 is not its eigenvalue (actually, the statement in [OS1] is formulated for $m \geq 3\frac{N-1}{2}$ but the proof works also for $m = 3\frac{N-1}{2} - 1$), while in the sectors $\frac{N+1}{2} + 2 \leq m \leq 2\frac{N+1}{2}$, the operator $L$ has negative eigenvalues. Now observe that the sectors with $\frac{N+1}{2} \leq m \leq 3\frac{N-1}{2} - 2$ do not have $C_{Nv}$ symmetry and consequently forbidden in our case. Thus on the subspace invariant under action of the group $C_{Nv}$, $L \geq 0$ and 0 is now its eigenvalue. The latter implies that

$$E_R(a) - E_R(0) > 0 \quad (A4.2)$$

for any odd $N$ and for $a$ sufficiently small.

**Appendix 5. Large N asymptotics**

In this appendix we find asymptotic behaviour of the energy of the circular, asymptotically forceless configurations, i.e. the ones with $\nabla H(a) = 0$, for large values of $N$. More precisely, the configurations we consider consist of $N$ 1-vortices equally spaced on the circle of radius $a$ and with the center at the origin and one ($-k$)-vortex at the center. Recall that the condition $\nabla H(a) = 0$ is equivalent to the relation $k = -\frac{1}{2}(N - 1)$. We assume in addition that $N$ is odd and $a \gg N$.  

37
According to Eqn (5.10) and since \( \sin \frac{\pi k}{N} = \sin \frac{\pi (N-k)}{N} \), the energy of the above configuration is

\[
E_R(a) = \pi \left( \frac{N + 1}{2} \right)^2 \ln R - \pi \left( \frac{N - 1}{2} \right)^2 \ln \left( \frac{N - 1}{2} \right) + Nc(1)
\]

\[-2\pi N \sum_{k=1}^{N^2} \ln \left( 2 \sin \frac{\pi k}{N} \right),
\]

where, recall, we use the notation \( E_R(a) = E_R(\bar{a}) \). For \( a = 0 \) (the “initial state”) the energy is given by Eqn (3.5):

\[
E_R(0) = \pi \left( \frac{N + 1}{2} \right)^2 \ln R - \pi \left( \frac{N + 1}{2} \right)^2 \ln \left( \frac{N + 1}{2} \right).
\]

In order to calculate the sum in Eqn (A5.1) we use the Euler expansion

\[
\sum_{k=M}^{L} f(k) = \int_{M-\frac{1}{2}}^{L+\frac{1}{2}} f(x)dx - \frac{1}{24} \left( f'(L + \frac{1}{2}) - f'(M + \frac{1}{2}) \right).
\]

and two equalities

\[
\int_{0}^{\pi/2} \ln(2 \sin x)dx = 0,
\]

we obtain

\[
\sum_{k=1}^{N^2} \ln \left( 2 \sin \frac{\pi k}{N} \right) = \int_{\frac{1}{2}}^{\frac{\pi}{2}} \ln \left( 2 \sin \frac{\pi x}{N} \right)dx + \frac{1}{24} \cdot \frac{\pi}{N} \cot \frac{\pi}{2N}
\]

\[
= -\frac{N}{\pi} \int_{0}^{\pi/2N} \ln(2 \sin y)dy + \frac{\pi}{24N} \cot \frac{\pi}{2N}.
\]

For \( N \gg 1 \), this yields modulo terms \( O(1) \) in \( N \)

\[
\sum_{k=1}^{N^2} \ln \left( 2 \sin \frac{\pi k}{N} \right) = \frac{1}{2} \ln N.
\]

As a result we have for the energy difference

\[
E_R(a) - E_R(0) = N \left[ C(1) + \left( \frac{1}{2} - \ln 2 \right) \pi \right]
\]

\[
= 0.183\pi N.
\]
Thus for single vortices on the circle the energy for $a$ large is greater than the energy for $a = 0$.
