# COURSE INTRODUCTION: <br> WHAT HAPPENS TO A QUANTUM PARTICLE ON A PENDULUM $\frac{\pi}{2}$ SECONDS AFTER IT IS TOSSED IN? 

DROR BAR-NATAN

Follows a lecture given by the author in the "trivial notions" seminar in Harvard on April 29, 1989.

#### Abstract

This subject is the best one-hour introduction I know for the mathematical techniques that appear in quantum mechanics - in one short lecture we start with a meaningful question, visit Schrödinger's equation, operators and exponentiation of operators, Fourier analysis, path integrals, the least action principle, and Gaussian integration, and at the end we land with a meaningful and interesting answer.

## 1. The Question

Let the complex valued function $\psi=\psi(t, x)$ be a solution of the Schrödinger equation

$$
\frac{\partial \psi}{\partial t}=-i\left(-\frac{1}{2} \Delta_{x}+\frac{1}{2} x^{2}\right) \psi \quad \text { with }\left.\quad \psi\right|_{t=0}=\psi_{0} .
$$

What is $\left.\psi\right|_{t=T=\frac{\pi}{2}}$ ?
In fact, the major part of our discussion will work just as well for the general Schrödinger equation,

$$
\frac{\partial \psi}{\partial t}=-i H \psi, \quad H=-\frac{1}{2} \Delta_{x}+V(x),\left.\quad \psi\right|_{t=0}=\psi_{0}, \quad \operatorname{arbitrary} T
$$

where:

- $\psi$ is the "wave function", with $|\psi(t, x)|^{2}$ representing the probability of finding our particle at time $t$ in position $x$.
- $H$ is the "energy", or the "Hamiltonian".
- $-\frac{1}{2} \Delta_{x}$ is the "kinetic energy".
- $V(x)$ is the "potential energy at $x$ ".

Date: This edition: March 27, 1999; First edition: April 29, 1989.

## 2. The Solution

The equation $\frac{\partial \psi}{\partial t}=-i H \psi$ with $\left.\psi\right|_{t=0}=\psi_{0}$ formally implies

$$
\psi(T, x)=\left(e^{-i T H} \psi_{0}\right)(x)=\left(e^{i \frac{T}{2} \Delta-i T V} \psi_{0}\right)(x)
$$

By Lemma 3.1 with $n=10^{58}+17$ and setting $x_{n}=x$ we thus get:

$$
\psi(T, x)=\left(e^{i \frac{T}{2 n} \Delta} e^{-i \frac{T}{n} V} e^{i \frac{T}{2 n} \Delta} e^{-i \frac{T}{n} V} \ldots e^{i \frac{T}{2 n} \Delta} e^{-i \frac{T}{n} V} \psi_{0}\right)\left(x_{n}\right)
$$

Now using Lemmas 3.2 and 3.3 we find that this is: ( $c$ denotes the ever-changing universal fixed numerical constant)

$$
c \int d x_{n-1} e^{i \frac{\left(x_{n}-x_{n}-1\right)^{2}}{2 T / n}} e^{-i \frac{T}{N} V\left(x_{n-1}\right)} \cdots \int d x_{1} e^{i \frac{\left(x_{2}-x_{1}\right)^{2}}{T T / n}} e^{-i \frac{T}{N} V\left(x_{1}\right)} \int d x_{0} e^{i \frac{\left(x_{1}-x_{0}\right)^{2}}{2 T / n}} e^{-i \frac{T}{N} V\left(x_{0}\right)} \psi_{0}\left(x_{0}\right) .
$$

Repackaging, we get

$$
\psi(T, x)=c \int d x_{0} \ldots d x_{n-1} \exp \left(i \frac{T}{2 n} \sum_{k=1}^{n}\left(\frac{x_{k}-x_{k-1}}{T / n}\right)^{2}-i \frac{T}{n} \sum_{k=0}^{n-1} V\left(x_{k}\right)\right) \psi_{0}\left(x_{0}\right) .
$$

Now comes the big novelty. keeping in mind the picture

and replacing Riemann sums by integrals, we can write

$$
\psi(T, x)=c \int d x_{0} \int_{W_{x_{0} x_{n}}} \mathcal{D} x \exp \left(i \int_{0}^{T} d t\left(\frac{1}{2} \dot{x}^{2}(t)-V(x(t))\right)\right) \psi_{0}\left(x_{0}\right),
$$

where $W_{x_{0} x_{n}}$ denotes the space of paths that begin at $x_{0}$ and end at $x_{n}$,

$$
W_{x_{0} x_{n}}=\left\{x:[0, T] \rightarrow \mathbb{R}: x(0)=x_{0}, x(T)=x_{n}\right\}
$$

and $\mathcal{D} x$ is the formal "path integral measure".
This is a good time to introduce the "action" $\mathcal{L}$ :

$$
\mathcal{L}(x):=\int_{0}^{T} d t\left(\frac{1}{2} \dot{x}^{2}(t)-V(x(t))\right) .
$$

With this notation,

$$
\psi(T, x)=c \int d x_{0} \psi_{0}\left(x_{0}\right) \int_{W_{x_{0} x_{n}}} \mathcal{D} x e^{i \mathcal{L}(x)}
$$

Let $x_{c}$ denote the path on which $\mathcal{L}(x)$ attains its minimum value, write $x=x_{c}+x_{q}$ with $x_{q} \in W_{00}$, and get

$$
\psi(T, x)=c \int d x_{0} \psi_{0}\left(x_{0}\right) \int_{W_{00}} \mathcal{D} x_{q} e^{i \mathcal{L}\left(x_{c}+x_{q}\right)} .
$$

In our particular case $\mathcal{L}$ is quadratic in $x$, and therefore $\mathcal{L}\left(x_{c}+x_{q}\right)=\mathcal{L}\left(x_{c}\right)+\mathcal{L}\left(x_{q}\right)$ (this uses the fact that $x_{c}$ is an extremal of $\mathcal{L}$, of course). Plugging this into what we already have, we get:

$$
\psi(T, x)=c \int d x_{0} \psi_{0}\left(x_{0}\right) \int_{W_{00}} \mathcal{D} x_{q} e^{i \mathcal{L}\left(x_{c}\right)+i \mathcal{L}\left(x_{q}\right)}=c \int d x_{0} \psi_{0}\left(x_{0}\right) e^{i \mathcal{L}\left(x_{c}\right)} \int_{W_{00}} \mathcal{D} x_{q} e^{i \mathcal{L}\left(x_{q}\right)} .
$$

Now this is excellent news, because the remaining path integral over $W_{00}$ does not depend on $x_{0}$ or $x_{n}$, and hence it is a constant! Allowing $c$ to change its value from line to line, we get

$$
\psi(T, x)=c \int d x_{0} \psi_{0}\left(x_{0}\right) e^{i \mathcal{L}\left(x_{c}\right)}
$$

Lemma 3.4 now shows us that $x_{c}(t)=x_{0} \cos t+x_{n} \sin t$. An easy explicit computation gives $\mathcal{L}\left(x_{c}\right)=-x_{0} x_{n}$, and we arrive at our final result:

$$
\psi\left(\frac{\pi}{2}, x\right)=c \int d x_{0} \psi_{0}\left(x_{0}\right) e^{-i x_{0} x_{n}}
$$

Notice that this is precisely the formula for the Fourier transform of $\psi_{0}$ ! That is, the answer to the question in the title of this document is "the particle gets Fourier transformed", whatever that may mean.

## 3. The Lemmas

Lemma 3.1. For any two matrices $A$ and $B$,

$$
e^{A+B}=\lim _{n \rightarrow \infty}\left(e^{A / n} e^{B / n}\right)^{n}
$$

Proof. (sketch) Using Taylor expansions, we see that $e^{\frac{A+B}{n}}$ and $e^{A / n} e^{B / n}$ differ by terms at most proportional to $c / n^{2}$. Raising to the $n$th power, the two sides differ by at most $O(1 / n)$, and thus

$$
e^{A+B}=\lim _{n \rightarrow \infty}\left(e^{\frac{A+B}{n}}\right)^{n}=\lim _{n \rightarrow \infty}\left(e^{A / n} e^{B / n}\right)^{n}
$$

as required.

## Lemma 3.2.

$$
\left(e^{i t V} \psi_{0}\right)(x)=e^{i t V(x)} \psi_{0}(x)
$$

Lemma 3.3.

$$
\left(e^{i \frac{t}{2} \Delta} \psi_{0}\right)(x)=c \int_{3} d x^{\prime} e^{i \frac{\left(x-x^{\prime}\right)^{2}}{2 t}} \psi_{0}\left(x^{\prime}\right) .
$$

Proof. In fact, the left hand side of this equality is just a solution $\psi(t, x)$ of Schrödinger's equation with $V=0$ :

$$
\frac{\partial \psi}{\partial t}=\frac{i}{2} \Delta_{x} \psi,\left.\quad \psi\right|_{t=0}=\psi_{0}
$$

Taking the Fourier transform $\tilde{\psi}(t, p)=\frac{1}{\sqrt{2 \pi}} \int e^{-i p x} \psi(t, x) d x$, we get the equation

$$
\frac{\partial \tilde{\psi}}{\partial t}=-i \frac{p^{2}}{2} \tilde{\psi},\left.\quad \tilde{\psi}\right|_{t=0}=\tilde{\psi}_{0}
$$

For a fixed $p$, this is a simple first order linear differential equation with respect to $t$, and thus,

$$
\tilde{\psi}(t, p)=e^{-i \frac{t p^{2}}{2}} \tilde{\psi}_{0}(p)
$$

Taking the inverse Fourier transform, which takes products to convolutions and Gaussians to other Gaussians, we get what we wanted to prove.

Lemma 3.4. With the notation of Section 2 and at the specific case of $V(x)=\frac{1}{2} x^{2}$ and $T=\frac{\pi}{2}$, we have

$$
x_{c}(t)=x_{0} \cos t+x_{n} \sin t
$$

Proof. If $x_{c}$ is a critical point of $\mathcal{L}$ on $W_{x_{0} x_{n}}$, then for any $x_{q} \in W_{00}$ there should be no term in $\mathcal{L}\left(x_{c}+\epsilon x_{q}\right)$ which is linear in $\epsilon$. Now recall that

$$
\mathcal{L}(x)=\int_{0}^{T} d t\left(\frac{1}{2} \dot{x}^{2}(t)-V(x(t))\right)
$$

so using $V\left(x_{c}+\epsilon x_{q}\right) \sim V\left(x_{c}\right)+\epsilon x_{q} V^{\prime}\left(x_{c}\right)$ we find that the linear term in $\epsilon$ in $\mathcal{L}\left(x_{c}+\epsilon x_{q}\right)$ is

$$
\int_{0}^{T} d t\left(\dot{x}_{c} \dot{x}_{q}-V^{\prime}\left(x_{c}\right) x_{q}\right) .
$$

Integrating by parts and using $x_{q}(0)=x_{q}(T)=0$, this becomes

$$
\int_{0}^{T} d t\left(-\ddot{x}_{c}-V^{\prime}\left(x_{c}\right)\right) x_{q} .
$$

For this integral to vanish independently of $x_{q}$, we must have $-\ddot{x}_{c}-V^{\prime}\left(x_{c}\right) \equiv 0$, or

$$
\ddot{x}_{c}=-V^{\prime}\left(x_{c}\right) . \quad\binom{\text { This is the famous } F=m a \text { of Newton's, and we }}{\text { have just rediscovered the principle of least action! }}
$$

In our particular case this boils down to the equation

$$
\ddot{x}_{c}=-x_{c}, \quad x_{c}(0)=x_{0}, \quad x_{c}(\pi / 2)=x_{n}
$$

whose unique solution is displayed in the statement of this lemma.

## 4. The Morals

- Schrödinger's equation is related to some infinite dimensional "path integrals".
- These path integrals can sometime be evaluated, with interesting and useful results.
- The Fourier transform fits within some 1-parameter family of unitary operators, defined by $U_{t}=e^{-i t H}$ for $t$ other than $\frac{\pi}{2}$. The same techniques lead to explicit formulas for $U_{t}$ for any $t$.
- We'd better work harder, to understand how all of this fits into some bigger coherent picture.
